R. DESJACQUES, F. BÉRARD, and H. LATHURAZ-VIOLLET (*Rev. de Chir.*, November, 1930, p. 296) record 47 cases of rupture of the spleen associated with rupture of the left kidney. These cases occurred nearly always in the male sex, the most common age being between 10 and 20 years. The cause is seldom pathological, and is nearly always an accident, the condition resulting from severe trauma. Since the kidney is firmer and less friable than the spleen, it does not usually suffer so much damage in an abdominal injury. It is nearly always necessary to remove the spleen, and in 13 cases in which this was not done death invariably occurred. In 33 cases the capsule was ruptured, and in two instances the spleen was crushed; in another case it was found to be torn at the junction of the upper third with the lower two-thirds, the upper pole being almost completely separated. Lesions of the kidney are frequently less serious than those of the spleen; in the majority of cases the capsule only is ruptured, but in eight of the cases reported it was torn from its pedicle. There may be associated lesions in other organs, such as the liver, pancreas, or diaphragm. The most noticeable symptom is that of shock, and death may occur quickly from severe internal haemorrhage, of which the chief signs are a progressive weakness, pallor, coldness of the limbs, a rapid pulse, and a variable temperature. Pain is felt in the left flank, and may be generalized over the whole abdomen; it may also be localized in the lumbar region, or referred to the left shoulder. Ecchymosis may also be present, and palpitation will provoke abdominal pain and contraction of the abdominal wall, which may be localized in the splenic area. Abdominal meteorism may be observed, and percussion of the abdomen may reveal dullness in the left flank in 25 per cent. of cases. The prognosis is grave; out of the 47 cases under review 32 patients (68 per cent.) died. Treatment, which must be surgical, depends mainly for its success upon the condition of the spleen, and also upon the rapidity with which an operation can be undertaken. In cases where no operative treatment was employed, or where the kidney only was dealt with, the mortality was 10 per cent. When the spleen alone was removed the mortality was reduced to 57 per cent., and when operation included the spleen and the kidney only 50 per cent. of deaths are recorded.

53 Diaphragmatic Paralysis by Phrenic Evulsion

H. WILSON (*Med. Journ. of Australia*, October 11th, 1930, p. 487) presents a critical review of phrenic evulsion in 200 patients, including the indications for and the results of the operation. The diagnosis of diaphragmatic paralysis is best made by radiology. There is no direct physical sign of unilateral paralysis, but a combination of signs gives indirect evidence; when the thorax is grossly altered, diagnosis may be impossible. Hemidiaphragmatic paralysis on the same side always occurs after phrenic evulsion; the paralysed side rises higher than its fellow, and may continue to rise for six months after the operation. If no gross thoracic alteration exists, the elevation of the paralysed side is influenced by the patient's physique and habitude. The degree to which the paralysed half rises is greater on the right side than on the left, and the paralysis is permanent if more than 2.5 cm. of the nerve is evulsed. The size of the pleural cavity and the lung volume are diminished by phrenic evulsion; this results in relaxation and resting of the whole lung. Compression of the lower pulmonary lobe also ensues, and an average reduction of 18 per cent. of the actual vital capacity follows. The reduction is greatest when the pulmonary disease is not extensive. Untoward symptoms after this operation are rare; slight increase of pre-existing dyspnoea occasionally occurs, but is rarely sufficient to cause complaint or disability. Wilson considers phrenic evulsion a valuable adjunct to thoracoplasty; it produces better collapse in cases of artificial pneumothorax with basal diaphragmatic adhesions. When refills have to be given frequently, it lengthens the interval between them, but in the pneumothorax treatment of phthisis its value in decreasing the incidence of pleural effusion is doubtful, and the results of combined phrenic

evulsion and artificial pneumothorax in bronchiectasis have been disappointing. Marked pulmonary collapse may be obtained with only slight improvement in the amount of sputum and fetor. In pulmonary tuberculosis, this operation benefits the local lesion, toxaemia, and haemoptysis, but only slightly influences the amount of sputum. In bronchiectasis phrenic evulsion alone causes but little benefit. It is of value in assisting drainage from lung abscess and interlobar empyema; it should be considered also in treating pain due to pleural adhesions, and as a palliative measure in pleuro-pericardial adhesions.

54 Varieties of Gall-stone Ileus

O. LUTTEROTTI (*Wien. klin. Woch.*, November 13th, 1930, p. 1399) states that obstruction of the small intestine, especially of the ileum, is the commonest accident to follow ulceration of a gall-stone into the alimentary canal; he cites some illustrative cases. Volvulus also occurs, and may be due to the stone weighing down a loop of intestine into the pelvis and causing kinking. This may also explain some of the cases of obstruction without volvulus, since in one recorded case the stone was palpated through the vagina, dislodged digitally, and later passed per rectum. A gall-stone in the intestine may reach a hernial sac and here cause obstruction owing to narrowing of the gut, without strangulation of the hernia ensuing. Pyloric obstruction due to a gall-stone is a rare condition. The stone in this case may have ulcerated directly into the stomach, or may have been vomited into the stomach from the duodenum. Large intestine obstruction, again, may be due to direct ulceration into the colon, or the stone may have come through the small gut without mishap. It must be remembered here that the mass tends to increase in size on its way down owing to incrustation. The mortality in all recorded cases of gall-stone ileus is serious (56 to 64 per cent.), owing to the high average age of the patients and the advanced stage at which they usually arrive at operation.

55 Milkers' Whitlow

A. KITTINGER (*Zentralbl. f. Chir.*, November 29th, 1930, p. 2980), who records an illustrative case, states that this condition has received little attention owing to its essentially mild character, which allows the milkman to continue his occupation. It is frequently met with in large dairies among the milkers and those employed in cleaning the cows. The whitlow is produced by the fissures in the callosities on the flexor aspects of the milkers' hands becoming inflamed, the irritation being kept up by penetration of small hairs from the cow's udder during milking. Histological examination reveals plasma cells, a large quantity of lymphocytes and pus cells, and inclusion bodies containing fragments of hairs and detritus. Kittinger's patient contracted a subungual whitlow of the right thumb, complicated by periostitis and osteitis. The man was able to resume his work three weeks after an operation, when granulation tissue and masses of fine hairs were removed with a sharp spoon.

Therapeutics

56 The Ketogenic Treatment of Epilepsy

H. F. HELMHOLZ and H. M. KEITH (*Journ. Amer. Med. Assoc.*, September 9th, 1930, p. 707) tabulate the results of treatment by the ketogenic diet method between 1921 and 1930 in the case of 243 children suffering from idiopathic epilepsy. In a former report (1927) cases were classified as (1) free from attacks for a year or more; (2) definitely benefited; (3) not improved. In the present report two cases formerly in class (1) now appear in class (2) on account of recurrence of symptoms after return to a normal diet, though it has been found, as a rule, that freedom from symptoms for nine to twelve months under dietetic treatment is followed by freedom after return to a normal diet. Of the total number treated, 72 are excluded on account of failure to follow the strict diet; of the remaining 171, 30 have been treated for less than one year, and of 141 treated for more than one year, 43 come into class (1), 32 into class (2), and 66 into class (3). Inquiry has been made into the present status of cases reported on in 1927. Of 18 free from attacks for more than one year, 16 remain well on a normal diet, and 2 have been transferred to class (2) on account of recurrences. Of 8 free for less than one year, 5 have had no attacks, 2 show improvement, and 1 has not persevered with the diet. Three patients had recurrences after returning to a normal diet; one has had no more attacks, one has improved, and one has not persevered. Of 20 patients who showed improvement only, 1 has had no attacks, 4 show further improvement, 9 are not benefited, and 6 did not persevere. It has been found that patients who need to be kept constantly in ketosis, in order to be free from attacks, do not tend to cure, and often show no improvement on return to normal diet. Dehydration has not been found to lessen the frequency of attacks. It has been found experimentally that the exhibition of ketone bodies protects animals from the action of convulsant drugs. In certain cases where dieting alone has been insufficient to control attacks, the combination of diet with the exhibition of phenobarbital has given better results than the use of diet or drugs alone. The proportion to the total number of cases treated of the three classes already mentioned is the same in the later series as in that previously reported.

57 Intravenous Administration of Morphine

M. SALZER (*Med. Journ. and Record*, November 5th, 1930, p. 452) advocates the intravenous injection of morphine, slowly given, as a safe and certain method of providing immediate relief in cases of colic and cardiac distress, without exceeding the requisite minimum dose. Half a grain of morphine in solution is very slowly injected into the vein, and the syringe is withdrawn as soon as complete relief is obtained; this occurs much more rapidly than when the alkaloid is administered by the subcutaneous route, and the effects last as long. The value of this procedure is obvious in those cardiac cases where the time factor is of the greatest importance if any chance of saving life is to be taken. Besides being of value in cases of biliary or renal colic, where the aim is to obtain immediate relief with a sufficient dose and no more, it is of use in cases of coronary occlusion, angina pectoris, and acute pulmonary oedema due to acute decompensation.

58 Serotherapy in Meningococcal Septicaemia

CODVELLE and FERRABOUC (*Rev. Méd. Française*, October 1930, p. 707) analyse the results in twelve cases of meningococcal septicaemia, personally treated by them, and considered from the clinical, bacteriological, and therapeutic standpoints. The different forms of treatment employed are grouped as: (1) specific, which includes serotherapy, vaccinotherapy, and autotherapy; and (2) the anti-infective. The second (non-specific) group comprises shock methods, such as chemotherapy with metallic colloids, diamino-methyl-acridine hydrochlorate (gonacrine), and fixation abscess. The authors disclaim any therapeutic discovery, admitting the smallness of the numbers of each group which were tested, but they express a preference for early intraspinal serotherapy. They call attention, however, to the risk of sensitizing thus the meningeal tissues, and emphasize the need for further research.

59 Acriflavine in Undulant Fever

D. S. THURBER (*Canadian Med. Assoc. Journ.*, November, 1930, p. 665) points out that treatment in undulant fever is an urgent problem, since this disease always incapacitates the patient for months and occasionally for years, and is frequently followed by disabling joint pains and arthritis. The use of acriflavine hydrochloride has been commended in Europe and in America. Thurber reports the results in 7 cases following intravenous injections of this salt, and in 7 untreated patients. In 5 of the former cases the fever was arrested within one month; in 2 the fever continued, but at a lower level. In the untreated cases the disease lasted from nine months to two years, and 2 ended fatally. The best results were obtained in

patients treated during the earlier weeks of the disease; chronic arthritis did not develop in such cases. If given after the development of arthritis, acriflavine seemed to have little or no effect on the condition. Tablets containing 0.1 or 0.3 gram of acriflavine hydrochloride should be dissolved in about 20 c.cm. of warm normal saline solution, immediately before use. An ordinary intravenous saline injection is first started to ensure proper entry into the vein, and then the 20 c.cm. of acriflavine solution is added to about 200 c.cm. of warm normal saline solution. The dosage varies according to the size, age, and condition of the patient, and the number of previous injections. The acriflavine must be administered slowly (5 c.cm. per minute) to avoid reactions. Following the injections, a decline, a rise, and a final decline in the fever occur. No severe reactions or harmful effects were noted. Thurber believes that by the intravenous use of acriflavine the course of undulant fever is materially shortened, and the development of an incapacitating arthritis prevented.

60 Vaccine Therapy in Enteric Fever

J. H. CROUCH (*Public Health Rep., Washington*, October 10th, 1930, p. 2429) states that during an epidemic of typhoid fever which occurred in Helena, Montana, in the latter part of 1929, 77 of the 216 cases received T A B vaccine, either just before the onset or during the course of the disease. With a very few exceptions, all received the first dose after the probable date of infection. A comparison of these 77 cases with 105 cases during the same epidemic which did not receive vaccine yielded the following results. (1) 22 patients who were given three doses of vaccine, the first of them before the onset of symptoms, had a definitely milder and shorter attack than any of the others, and no fatal cases occurred. (2) In 17 cases which had only one or two doses, the first of which was given before the symptoms started, the duration of the disease seemed to be shorter, but the severity was not less than in control cases, and there was one death. (3) A group of 21 cases in which the first dose was given shortly after the onset, but before the patient went to bed, showed very little variation from the controls as regards duration and severity, and one fatal case occurred. (4) In a group of 17 cases which received vaccine after going to bed the average duration was a few days less, but the severity of the attack was at least as great as in the control group, and there were two deaths. Crouch concludes that typhoid vaccine is well worth while when given after infection, provided the first dose in administered before the onset and three doses are given. After the onset vaccine is of little or no value.

Dermatology

61 Keratoma Senile and Verruca Senilis

Contrasting these two conditions, J. A. HOOKEY (*Proc. of the Staff Meetings of the Mayo Clinic*, August 27th, 1930, p. 239) states that keratoma senile affects men more often than women, and as a rule occurs after middle age; it is often associated with the changes of senile atrophy. The lesions, which are typical, are usually situated on the face, hands, and forearms, though they occur elsewhere on the body. They begin as small, sharply circumscribed yellow or brown spots, and may remain as such for years. After varying periods many lesions become elevated and covered with adherent, thick, grey scales, presenting on their undersurface projections which fit into minute depressions in the cutis. Usually more than one lesion is present. The lesions may develop into cornu cutaneum. Inflammation, when present, usually indicates a malignant change. Of 31 patients (19 men and 12 women), 8 showed malignant changes. Irregular hyperkeratosis and acanthosis are present in all cases. More important are the individual cell changes; the normal keratinization of the cells is disturbed and dyskeratotic cells are produced. Mitotic cell division is commonly seen; amitotic division also occurs, with the formation of giant cells with multiple clumped nuclei. Another type of giant epithelial cell has a large nucleus with granular chromatin and one or more nucleoli. Oedema of the prickle cell layer develops, but the basal cell layer is usually intact. Pigment in small amount may be found, particularly in the epidermal dendritic cells. The hair follicles and the sebaceous and sweat glands and ducts are normal. The duration of the lesions varied from 3 months to 16 years. Verruca senilis occurs usually on the trunk, especially in the seborrhoeic areas. The lesions are usually multiple and the patients elderly; when fully developed the lesions consist of yellow or brown patches with thin, greasy scales. They begin as small macules, which gradually increase in size and become deeply pigmented; they are often granular in appearance. Inflammation at the base and subjective symptoms are not common. Varying degrees of hyperkeratosis are present. Irregular acanthosis occurs with partial fusion of the rete ridges to form a network in which are found connective tissue islands and cyst-like spaces containing cornified material. Keratinization is not disturbed, and the basal cell layer is intact. The pigment (melanin) is found in and between the epidermal cells and in the chromatophores of the cutis. *No malignant changes* were detected in 52 cases (28 men, 24 women). The duration of the lesions ranged from 2 to 60 years. The differential diagnosis of these conditions is outlined. Senile changes in the skin, exposure to the sun and wind, and hereditary predisposition are etiological factors in keratoma senile, and malignancy arising in the latter affection is usually of the squamous cell type. Verruca senilis is not a precancerous lesion; it is best classed among the delayed naevi of the epithelial layer. The lesion is essentially an epithelial hyperplasia; under proper stimulus, such as continued irritation, it might possibly become malignant.

62 Acriflavine in Psoriasis Vulgaris

In 1928 OPPENHEIM reported the successful treatment of psoriasis with intravenous injections of trypaflavine combined with ultra-violet irradiation. The dye (acriflavine hydrochloride) was shown to have a strong photosensitizing effect, and was given to increase the action of the actinic rays. S. E. SWEITZER and P. K. ALLEN (*Minnesota Med.*, November, 1930, p. 818) report 20 cases of psoriasis vulgaris treated with intravenous injections of acriflavine. The acid salt was used, as the neutral one proved to be toxic. All but 3 of the cases showed clinical improvement; in 4 the results were striking. In no case in which the eruption disappeared entirely were violet rays used. Moreover, the lesions on the protected areas of the body showed involution as rapidly as those on the hands and arms, which were more exposed to actinic rays. All the patients who improved did so without the rays, though these undoubtedly enhanced the value of the procedure. In the 3 patients who showed no improvement with injections the addition of radiation produced no benefits. The results, therefore, were not entirely due to photosensitization. In treatment the authors dissolve 0.1 gram of the salt in 20 c.cm. of sterile distilled water, and inject this slowly. This dose was given three times weekly, and was always well tolerated. Involution of the lesions followed a definite course; there was a gradual flattening of the papules and a diminution of the scales, leaving a pigmented area. This pigmentation faded slowly, and was the last sign of the dermatitis to disappear.

63 Xanthoma Multiplex with Hypothyroidism

The rarity of the association of xanthomatosis and hyperthyroidism has induced J. F. CHRISTIE, A. LYALL, and T. E. ANDERSON (*Brit. Journ. of Dermatol. and Syph.*, October, 1930, p. 429) to record the case of a woman, aged 44, who was stout, slow, and of placid habit; she was admitted to hospital in October, 1929, on account of multiple xanthomatous deposits on the hands, feet, and arms which had been present for a year. The size of the lesions varied from that of a hazel nut on the palms and soles to that of a split pea elsewhere. The patient had suffered from digestive troubles of an indefinite sort for twenty years, but a general physical examination showed no abnormality.

Examination of the blood showed it to be normal (including a normal sugar tolerance curve) except for a cholesterol content of 426 mg. per 100 c.cm. (normal high limit 200 mg. per 100 c.cm.). A dietary poor in fat was given for a month with no effect on the skin lesions or the blood cholesterol, and the definite lipaemia persisted. Insulin treatment having been previously shown to clear up lipaemia in diabetics, it was given a trial; although a single dose did not cause hypoglycaemia, some faintness followed, and the patient refused further injections. In November the basal metabolic rate was found to be 27 per cent. below normal, and thyroid gland, up to 12 grain doses daily, was given. A rise in the metabolic rate followed, with a fall in the blood cholesterol, but there was no immediate improvement in the skin lesions. There was a subsequent rise in the cholesterol figure, but following discharge of the patient in the following January, on a daily dose of 10 grains of thyroid, it was found to have dropped to 228 mg. per 100 c.cm. in April, 1930, by which time there was a definite clinical improvement in the skin lesions. The authors consider that this case suggests a possible etiological factor in non-diabetic xanthoma.

Obstetrics and Gynaecology

64 Hormones of Gestation

E. PHILIPP (*Zentralbl. f. Gynäk.*, November 1st, 1930, p. 2754), while acknowledging that many gaps still exist in our knowledge of the hormonic activity and relations of the ovum, ovaries, decidua, and hypophysis during early pregnancy, puts forth the following scheme as representing conceptions which are justified at present. Prolan B (Zondek), a hormone produced in the cells of the early chorion (although not there alone), induces development of the corpus luteum of pregnancy. The consequent luteinization in the ovary is associated with copious production of a corpus luteum hormone, which Philipp terms "lutin" or progestin. This hormone causes the development of the decidua in the pre-gravid endometrium, in which further preparation for pregnancy had previously been inhibited by the pre-existing corpus luteum. The decidua regresses in the later months of pregnancy, with diminution in production of prolan B and degeneration of the corpus luteum of pregnancy. Prolan B is found in appreciable amounts in the placenta in man and apes only, and almost disappears towards term. It is admitted that prolan B is not a placental product only, but is also formed in the anterior lobe of the pituitary body, as shown in the work of Zondek and Aschheim. In Philipp's experiments now described the production of pre-gravid endometrial hypertrophy in castrated rabbits is taken as a test sign of corpus luteum hormone, a recommendation made by Corner, Allen, and Clauberg. Transplantation experiments have indicated that this hormone is absent from the placenta. The association of prolan B, originating in the chorion, with lutein formation in the pregnancy corpus luteum, gives an explanation of the frequently reported coexistence of hydatidiform mole (with chorionic overgrowth) and corpus luteum cysts of the ovary.

65 Pelvic Sympathectomy

BINET (*Bull. Soc. Obstét. et de Gynécol. de Paris*, October, 1930, p. 590) states that in thirty-two out of thirty-three trials he has found it easy to divide the pelvic sympathetic nerves. Instead of isolating and dividing the presacral nerve (as described by Cotte) he removes the whole of the cellular tissue, with the included sympathetic fibres, lying between the common iliac arteries. No cases of uterine carcinoma were included, but most of the patients suffered from intractable pain. In nearly all of them uterine haemorrhage occurred from the second to the fifth day after operation. Relief of pain was usually secured among those suffering from dysmenorrhoea or from dyspareunia. According to A. HAMANT (ibid., p. 593), resection of the presacral nerve is a comparatively simple operation which is usually effective. Metrostaxis a few days afterwards is constant, and is to be regarded as a sign that the sympathetic fibres have really been divided. In dysmenorrhoea the results are said to be very good. In certain cases other surgical measures are carried out at the operation—for example, appendicectomy, division of adhesions, and uterofixation. In other cases, of which an example is cited, presacral resection alone is effective. When there is carcinoma of the uterus Hamant has obtained much relief from pain by combining resection of the presacral nerve with periarterial sympathectomy. V. RICHE and G. FAYOT (ibid., p. 575) report eight cases of resection of the presacral nerve. Their results were: in two cases of cancer of the uterus, no improvement; in a case of essential pelvic neuralgia, some amelioration; in five cases of dysmenorrhoea, cure in two, relief in two, and no change in one.

66 Gestation in Generalized Neurofibromatosis

M. V. MOREIRA (*Gynécol. et Obstét.*, September, 1930, p. 229) describes a case showing the effects of repeated pregnancies on a woman with von Recklinghausen's disease. The patient was 28 when first seen by him, and no other member of the family had been similarly affected. She had given birth previously to two children; both pregnancies, confinements, and puerperia had been normal. At the age of 10 years a small subcutaneous tumour had appeared on the face; it was painless, and grew only to the size of a hazel nut. This constituted the sole manifestation of the malady for twelve years. During the three months after her first confinement pigmentation appeared, the first being a patch on the arm with, subsequently, other patches on the back and front of the trunk. These persisted until her second pregnancy five years later. During this pregnancy the pigmentation again increased, but regressed after the confinement. During the third month of the third pregnancy the woman noted the appearance of cutaneous tumours on the unpigmented skin areas, and also an extension of the existing pigmentation, with a number of asymmetrically placed bronze patches of variable size. There were many small tumours of different sizes, most being distributed over the back. The patient eventually gave birth to healthy twins, the confinement and puerperium being normal. The spots of pigmentation on the face gradually diminished, but there was no modification of the tumours. The patient presented no signs of intoxication, of infection, or of nervous involvement, apart from a certain amount of apathy. Moreira remarks that since pregnancy augmented the disease, the possibility of the ductless glands being concerned must be considered. The ovaries appeared to function normally, as the pregnancies were normal. The prognosis would have to be reserved because the pelvic basin might not remain normal as at present. Although the patient had been affected for eighteen years, no cachexia was observable. It appears that if the influence of pregnancy on the evolution of the malady was incontestable, the malady itself had no influence on the function of reproduction.

67 Extrauterine Pregnancy

After briefly discussing the etiology, pathogenesis, diagnosis, and treatment of extrauterine pregnancy, J. C. MASSON (*Minnesota Med.*, November, 1930, p. 822) records the antecedent and subsequent histories in 471 such cases. These occurred at the Mayo Clinic during a period of twenty-five years. The youngest patient was aged 15 and the oldest 52, the average age being nearly 32. In 20 cases the ovum was still developing in the tube when the operation was performed. There were 7 cases of abdominal pregnancy, in 3 of which the pregnancy had reached full term. Lithopedions were found in 10 cases. Three cases of bilateral tubal pregnancy occurred, and one of twin pregnancy in one tube. Cases of associated intra- and extrauterine pregnancy were not found. The average length of married life was almost nine years. Masson agrees that previous sterility and abnormal pregnancy are important etiological factors: 109 patients (23.14 per cent.) did not give a history of previous uterine pregnancy, and 53 gave one of only miscarriages or ectopic pregnancies. Previous pelvic disease was present in 221 cases (46.9 per cent.). The average length of time from the last menses to the

onset of symptoms was about 10½ weeks. Pain was the chief complaint in 278 patients (62.32 per cent.), and vaginal bleeding in 160 (36.03 per cent.). The following average findings are given: blood pressure, 118.56 systolic and 82.61 diastolic; pulse 90.5; temperature 98.84° F.; haemoglobin 66.41 per cent.; and the leucocyte count 9,080. Six deaths followed operation, an operative mortality of 1.27 per cent. Two other patients, admitted *in extremis*, died from haemorrhage before being operated on. In 2 cases early tubal abortion was found accidentally at necropsy; one patient had died from acute nephritis, the other from oesophageal cancer. In a previous paper the subsequent pregnancies in 198 cases of ectopic gestation were reported; in 87 of these (44 per cent.) pregnancy again occurred. The total number of pregnancies was 162, 111 of which were normal. In 34 (20 per cent. of the 162) the pregnancies were intrauterine, but terminated in miscarriages. Eighteen pregnancies (less than 12 per cent. of the 162) were extrauterine. Masson believes, therefore, that bilateral salpingectomy is not justifiable for extrauterine pregnancy if the opposite tube is apparently fairly normal.

Pathology

68 Insulin and Epinephrine in Fasting Children

L. SALOMONSEN (*Amer. Journ. Dis. Child.*, October, 1930, p. 718) carried out eight experiments on healthy, fasting children, from 1 to 3 years old, with small doses of insulin. Hunger itself brings about a rapid fall in blood sugar and considerable ketonaemia in small children. The insulin was administered when the acetone curve was rising, and the blood sugar curve was either falling or had reached its minimum value. The insulin produced a further fall in the already low blood sugar content, while the blood acetone curve was unquestionably inhibited. However, the lower the blood sugar content was at the beginning of the experiment, the less marked was this effect; it appeared later and was less pronounced. The content of fatty acids in the blood plasma was shown, in two experiments, to fall if the blood acetone fell, and to remain unaltered if the acetone curve continued to rise after the injection of insulin. Seven experiments were performed on these children with epinephrine, injected subcutaneously in 0.1 per cent. solution. In all the experiments the blood sugar showed an immediate rise, of considerable extent and of short duration, reaching the maximum one or two hours after the injection. In all cases there occurred a distinct and temporary rise in the acetonaemia, the peak being attained an hour after that of the blood sugar. The lower the content of blood sugar the greater and more rapid was the rise in acetonaemia. In five out of six experiments a distinct rise in the quantity of fatty acids in the blood plasma occurred in one hour, and in the sixth experiment two hours, after the injection of epinephrine.

69 Experimental Transmission of Colds by a Filterable Agent

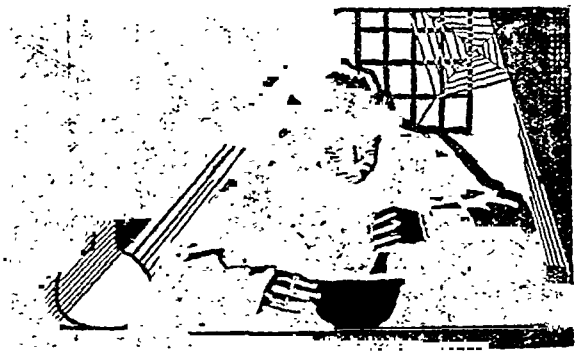
A. R. DOCHEZ, G. S. SHIBLEY, and KATHERINE C. MILLS (*Journ. Exper. Med.*, November, 1930, p. 701) have succeeded in transmitting the common cold to chimpanzees and human volunteers by means of filtered nasal washings from patients suffering from colds. A colony of chimpanzees was established under the most careful conditions of quarantine. After a period of preliminary observation, during which their nasal and nasopharyngeal flora was studied, they were submitted to experimental testing. Nasal washings were obtained from subjects with colds of not more than twenty-four hours' duration; these were passed through a Berkefeld V candle, and 1 c.cm. of the filtrate was injected into each nostril of the chimpanzee; the injections were repeated a few hours later. In positive experiments the first symptoms of a cold developed thirty-six to forty-eight hours later; the clinical picture that resulted was similar to that of a cold in a child. Examination of the nasal flora showed that with the onset of the cold a definite alteration occurred, characterized chiefly by the appearance of pneumococci in the nose and their rapid development to become the predominating organisms, together with a conspicuous increase in the numbers of Pfeiffer's bacillus. Of a total of 16 chimpanzees experimentally inoculated, 7 developed definite colds. Similar experiments in human volunteers kept in strict isolation resulted in 4 successful transmissions out of 9 attempts. It is noteworthy that no change in the nasal flora of the human volunteers was met with corresponding to that seen in the chimpanzees. The filtrates used generally contained anaerobic filter-passing organisms of the type described by Olitsky and Gates, but the authors do not regard these as having any etiological significance, because they were also present in control filtrates from healthy persons which gave negative results in chimpanzees, because two experiments made with pure cultures of these organisms failed to give rise to colds, and because some filtrates which proved infective were free from these organisms. The authors conclude that certain types of cold are caused by an ultra-microscopic filterable virus.

70 The Complement Fixation Test in Gonorrhoea

R. FÖRSTER (*Münch. med. Woch.*, October 31st, 1930, p. 1877), from a study of 1,350 serums, concludes that the complement-fixation reaction for gonorrhoea, if correctly performed (by Cohn's method) and interpreted, is of very considerable value in diagnosis and prognosis, and in controlling treatment. His main conclusions are as follows. In the early stages of the disease a negative reaction has no significance. A strongly positive reaction is evidence of present or recent gonorrhoea, a very useful point in the diagnosis of arthritic and gynaecological diseases. The reaction is only of diagnostic significance if specific vaccine treatment has not been employed. If a strongly positive reaction continues, it is evidence of latent infection remaining which may give trouble later on. A positive reaction becoming gradually negative during treatment is one sign of cure. A positive reaction is ordinarily to be considered as an indication for vaccine treatment.

71 Bacterially Produced Nervous Tissue Lesions

D. ORR (*Journ. Neurol. and Psychopathol.*, October, 1930, p. 97) states that he has shown that in lymphogenous infection of a peripheral nerve the lesion is interstitial in character, and the reaction is active at the site of the infection focus, becoming proportionately subacute and less active in the more remote portions of nerve. Experiments on seven rabbits, in which bacteria were introduced into the general circulation, are now recorded. These indicated that the resultant lesion in the nervous structures was degenerative or destructive, and involved definite cerebral anatomical sites. Necrotic areas in the fornix and cornu Ammonis were adopted as a criterion of the lesion. Definite necrotic areas were found in four of the seven brains examined; in the other three there was marked oedema, in spite of which coagulation necrosis was present. No haemorrhage was detected at or near the necrotic foci. In the cortex there were no gross lesions similar to the ischaemic softenings in the fornix and cornu Ammonis, but the nerve cells exhibited varying degrees of coagulation necrosis, which was not distributed uniformly throughout the cortex. In the superior and lateral areas of the pallidum the morbid changes varied in intensity, and all the cortical cell laminae were not involved in the necrotic change. The whole depth of the grey matter did not show nerve-cell necrosis. All the outer layers as far inwards as the ganglionic lamina were affected, but rarely the deepest or multiform layer. Granule and pyramidal cells were affected indescriminately. The pathogenesis is discussed, and the opinions of various authorities are cited. On this point the relation between the short cortical and long subcortical arterioles is important. Orr suggests that the localization of the lesions in the fornix and cornu Ammonis indicates that the vessels in these situations are terminal, while in the cortex, where the lesions are less marked and more diffuse, the absence of definite ischaemic lesions is due to the richness of the looped system of capillary supply.



Measuring Progress by the Therapeutic Yardstick

ANCIENT medicine set great store by "specifics." Paracelsus had his "Specificum Purgans." Cophon relied on mirobolanum or rhubarb in relieving constipation. Suppositories of honey and oxgall had their day in the fifteenth century.

Medicine has since made notable advances toward rationalism. In this day of therapeutic progress Agarol Brand Compound holds the foremost place. An exceptionally fine emulsion of mineral oil and agar-agar with phenolphthalein, it is not merely a laxative, but a remedial measure in the efficient treatment of constipation.

By introducing unabsorbable moisture, Agarol Brand Compound keeps the intestinal contents soft and makes their passage easy and painless. By *gentle stimulation* of peristalsis, it makes the result certain and aids in re-establishing normal bowel function.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

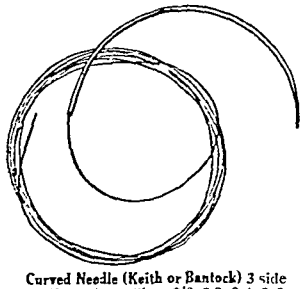
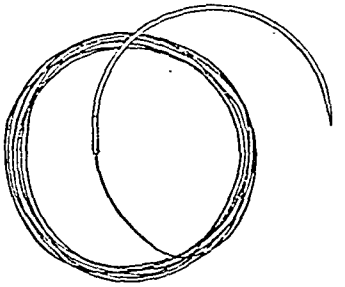
London Hospital Eyeless Needles

WITH L.H. CATGUT

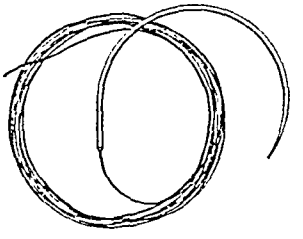
The London Hospital Eyeless Needles have been specially designed to avoid the doubling of the suture necessary in using needles with pierced eyes. They are fitted with tubular ends into which the sutures are firmly fixed, thus enabling the needles to be used with single strands. These needles are finely ground, sharp pointed and packed sterile in tubes for immediate use. Special precautions are taken to avoid any rusting of the needle after it has been packed.



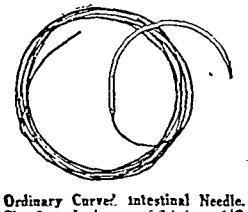
Curved Needle (Keith or Bantock) 3 side cutting edge. Sizes 3/0, 2, 0, 0, 1, 2, 3. In boxes of 3 tubes, **4/6**



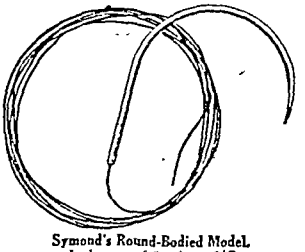
Curved Mayo Robson Stomach Needle. Sizes 4/0, 3/0, 2/0, 0, 1, 2, 3. In boxes of 3 tubes, **4/6**



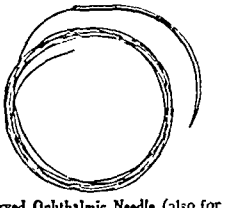
Moynihan's Model. In 3-tube box, **4/6**



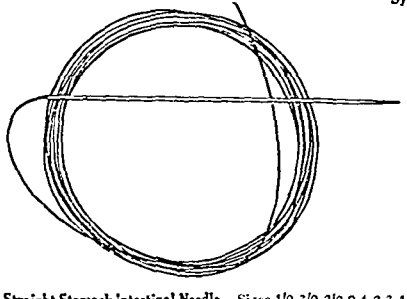
Ordinary Curved Intestinal Needle. Size 0 In boxes of 3 tubes, **4/6** In boxes of 3 cachets, **4/-**



Symond's Round-Bodied Model. In boxes of 3 tubes, **4/6**



Curved Ophthalmic Needle (also for plastic work). Size 6/0. In boxes of 3 tubes, **4/6**



Straight Stomach Intestinal Needle. Sizes 4/0, 3/0, 2/0, 0, 1, 2, 3, 4.
In boxes of 3 tubes with single needles, **4/6**

ACTINOTHERAPY

...A complete service rendered to the Medical Profession

THE VARIOUS MODELS OF HANOVIA QUARTZ LAMPS

FOR ACTINOTHERAPY

HANOVIA ALPINE SUN for general radiation. Administered to individual patients lying or standing.

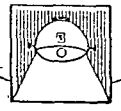
THE KROMAYER LAMP for local or artificial treatment.

JESIONEK QUARTZ LAMP for the treatment of groups of patients, in hospitals, clinics, etc.

THE PORTABLE HOMESUN LAMP for use in hospital wards or the patient's home, where roborant treatment is indicated.
This lamp is intended only for tonic purposes.

FOR LUMINOUS HEAT THERAPY

THE SOLLUX LAMPS for luminous heat therapy. Also frequently used in conjunction with Hanovia Quartz Lamps.



TWENTY-FIVE years' concentration on the most practical lamps for the administration of light therapy.

The steady accumulation of authentic information and its dissemination in reprint and magazine form.

Close co-operation consistently maintained with the Medical Profession throughout the world.

These among other factors have placed the Hanovia Company in its present unique position. To-day the name Hanovia is the mark of reliable actinotherapy equipment best suited to clinical needs.

Hanovia Service is by no means restricted to the supply of the latest equipment. The services of experienced agents are freely available when installations are being planned. Full assistance is given without obligation or expense. The wealth of clinical knowledge recorded in the Hanovia Reference Library is available for consultation by users. Particular emphasis is given to service after installation—every Hanovia user is at all times entitled to expect and receive full technical assistance to ensure best results from his lamp.

You cannot do better than send for a copy of Hanovia's new free prospectus, giving a full list of over 100 free reprints on this important subject. Send for your copy of this prospectus to-day, marking the enquiry Dept. 9.

167,000 HANOVIA Quartz Lamps in use the world over.

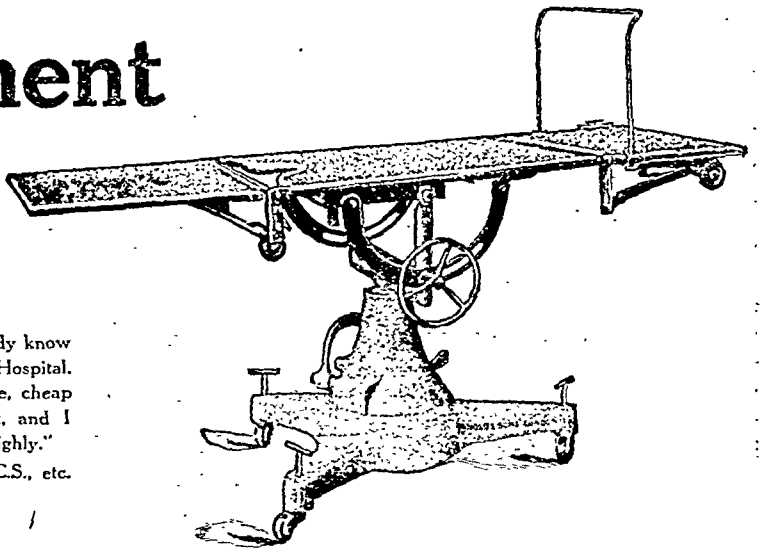
Hospital Equipment

by
ARNOLD & SONS
London



A London Surgeon writes:—

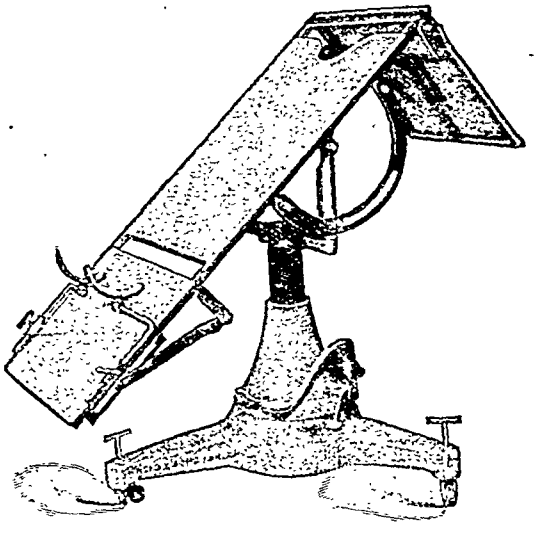
"Your Operating Table I already know well as we have one at the ——Hospital. It is far and away the best, simple, cheap operating table that I have met, and I should like to recommend it very highly."

Signed ——, F.R.C.S., etc.

The "ARNOLD" PEDESTAL OPERATION TABLE

A Matron writes:—

"The Table which you supplied for my Nursing Home is giving great satisfaction, and the Surgeons who work here find it convenient for all operations. It is just as useful for ear, nose and throat as for gynaecological ones. The advantage of your Table over others we have had is the rapidity with which the position of the patient can be changed without any strenuous work on the part of the Nursing Staff."



The "ARNOLD" TABLE
with lithotomy supports, shoulder rests, and douching funnel.

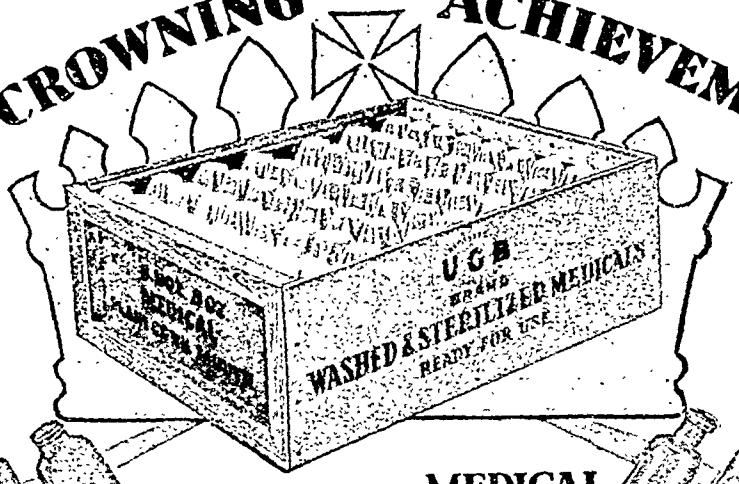
THE CROWNING ACHIEVEMENT



U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B. to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.

The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

Alimentary Toxæmia and Endocrine Insufficiency

A WRITER in *The Lancet* directed attention to an apparent connection between Alimentary Toxæmia and endocrine insufficiency, particularly of the thyroid gland. Many cases of "ill-health," neurasthenia and others, were benefited by the administration of thyroid extract.

Intestinal Disinfection

He goes on to remark that there seems to be a close connection between endocrine insufficiency and poisoning from intestinal absorption, and notes the beneficial results obtained by the use of intestinal antiseptics in addition in these cases.

He seems to be unaware that the best of all intestinal antiseptics is Kerol. In endocrine insufficiency, therefore, use Kerol in addition to other measures.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Emol-Keleet

Samples free to the Medical Profession on request.

FASSETT & JOHNSON, Ltd.
86, Clerkenwell Road, London, E.C.1.

Beneficial in Inflamed and Irritable Conditions of the Skin.

Emol-Keleet is a natural dusting powder of purely organic origin, combining a marked sedative action with absorbent, emollient and mildly astringent properties. It has a velvety-smooth texture and is remarkably adhesive. Emol-Keleet allays the itching of Eczema and dries up the exudations of "weeping" cases. It relieves the cutaneous irritation accompanying Measles and Scarlet Fever, and soothes any inflammation which may follow vaccination.

"STERULES" Regd.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is counter-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

Vapo-Cresolene Est. 1879

Sold by all Chemists

Write for descriptive Booklet No. 29.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

SIMPLE METHODS OF DIET CONTROL

The Energen starch-reduced and protein-increased dietary—including Bread, etc., and Cereal Health Foods—possesses the distinctive advantage of standardisation, each package bearing a statement of contents in grams of protein, carbohydrate and fat, and the total calorie value. Invaluable to the dietitian in the arrangement of special dietaries.

Prescribed throughout the English-speaking World in the dietetic treatment of defective metabolism; in the treatment of diseases of the Alimentary Tract; in cases of Carbohydrate Dyspepsia, Obesity, Rheumatism, Blood Pressure, etc. Standard in Diabetes.

These foods should be prescribed in all cases where the patient is placed on a light diet; in pre- and post-operative surgical dietetic treatment and in convalescence; as their extremely light and assimilable properties greatly improve the tonic condition.

A special scheme is in operation for supplies to Panel Patients at reduced cost.

The following Diet Tables sent post-free on receipt of post-card: for Diabetes (revised in accordance with the recent report prepared for the Medical Research Council (H.M. Privy Council) by McCance & Lawrence, on the Carbohydrate Content of Foods), for Obesity, and for Light Diets. Samples forwarded free of charge to patients, on request.

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: "*'Ardente' is a godsend to me*"; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

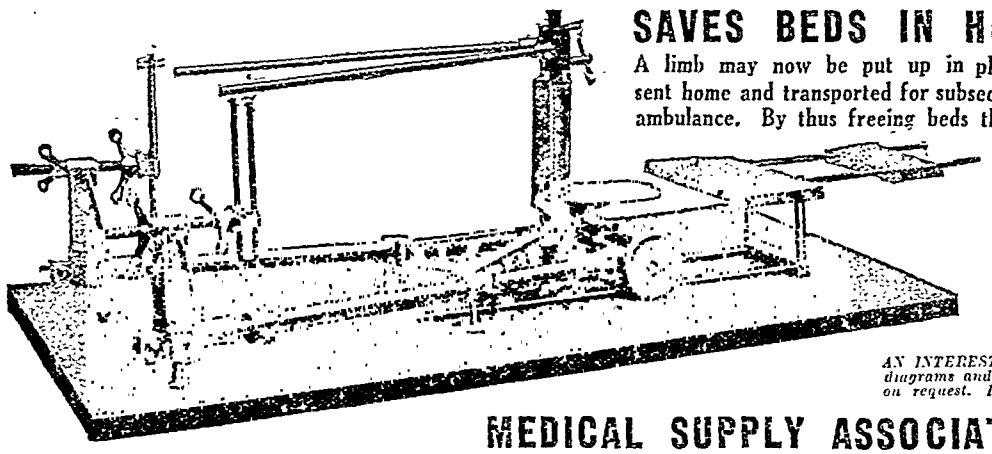
An IMPROVED and MODIFIED
Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

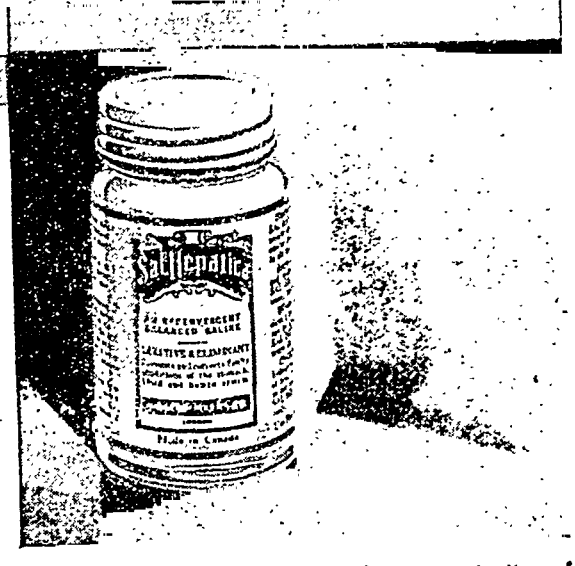
ESTABLISHES REGULAR EVACUATION



It is admitted that the large majority of patients suffer from the direct or indirect effects of constipation. It is often difficult to educate them to combat these evils. Some are ignorant, others apathetic, while many of them dread the griping pains and weakness occasioned by the ordinary laxatives. Sal Hepatica is pleasant to take and both prompt and painless in action. It maintains the biliary secretion in a healthy fluid state, and ensures freedom from congestion and from that sub-acute inflammation of the gall bladder which is at present so common, especially amongst sedentary workers. Sal Hepatica does not create a condition of tolerance. It is, therefore, the laxative of choice in chronic constipation.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol-Myers Company, 112, Cheapside, London, E.C.2.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Sal the proved Hepatica

d, medicinal, saline laxative and cholagogue.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,

SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

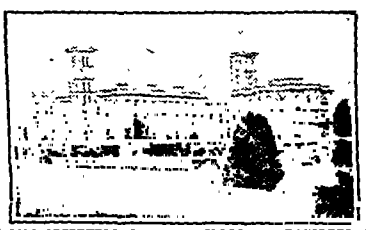
President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure and farm grounds, and is ready to receive patients. Application can now be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge.
Every facility for specialised investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.



King Edward VII Convalescent Home for Officers of the Navy, Royal Marines, Army, and Air Force.

RATIONAL REPETITION IN THE TREATMENT OF RHEUMATISM

For many years Pistany has been appreciated by the Medical Profession for its great work in the cure of Rheumatism.

The properties of Pistany's hot volcanic soft mud are quite peculiar. Its power of stimulating and increasing the absorption of pathological products is still unrivalled.

The treatment may be continued by the patient after returning from the Spa, under his own doctor's supervision, by means of the Mud Packs, which are in use in many rheumatism clinics in this country.

Markham Skerritt Memorial PRIZE.

This Prize, which is available for award this year, is open to that medical member of the University of Bristol who, not being a member of the Medical Board for the time being, in the opinion of that Board has in the three previous years published the best original work in any branch of medical science.
Applications are invited from those eligible to the Dean of the Faculty of Medicine.

United Services Fund.

HEATHERWOOD HOSPITAL, ASCOT.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from fully qualified Medical Practitioners (bachelor, not over 30) for the above post.
Candidates must have held some appointment in a General Hospital.
The present Hospital accommodation is 136 beds for the treatment of Surgical Tuberculosis and other forms of crippledom in children
The appointment will be for a period of twelve months and may be extended at the end of that time.
Remuneration is at the rate of £300 per annum, together with residence, board, and laundry.
The officer appointed will be required to devote the whole of his time to the duties of the office, to give anaesthetics, etc., and generally to act under the supervision and direction of the Medical Superintendent. Ample opportunities for study.
Applications, stating (1) age, (2) qualifications, (3) experience and appointments held, accompanied by three copies of recent testimonials, should be forwarded to the Secretary, Heatherwood Committee, United Services Fund, 29, Cromwell Road, South Kensington, London, S.W.7, not later than January 20th.
Further particulars can be supplied on application to the Medical Superintendent, Heatherwood Hospital, Ascot, Berks.

County Council of Durham.

SEAHAM HALL SANATORIUM.

MEDICAL SUPERINTENDENT.

The County Health Committee desire to receive applications for the post of Medical Superintendent of the above Institution, which has accommodation for about 80 female patients, and further accommodation is shortly to be provided by the Council for 50 additional beds.
The salary will be at the rate of £600 per annum, with furnished quarters and board, etc., valued at £150 per annum. In the case of a married man, the emoluments will be paid in cash, as there is accommodation (a cottage) for which a charge of £55 per annum is made by the County Council to cover rent, rates, and water.
The officer appointed must be a registered Medical Practitioner, and must devote whole time to the duties required of such person by the County Council. It is essential that the person appointed shall have held house appointments in a general hospital, and have had practical experience in the administration of a tuberculosis sanatorium and in the treatment of tuberculosis in such an institution, including X-ray and ultra-violet ray treatment, and in bacteriological laboratory work. Such officer must also be specially experienced in the orthopaedic treatment of non-pulmonary tuberculous cases.
The person appointed will be attached to the County Health Department and will be required, subject to the administrative control of the County Medical Officer of Health, to take full responsibility for the general management of the institution, including the supervision of the staff and the treatment of patients.
The appointment will be terminable by three months' notice on either side. A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to the successful candidate passing the County Council's medical examination in connection therewith.
Applications, endorsed "Medical Superintendent, Seaham Hall Sanatorium," with copies of not more than three recent testimonials, must be delivered to the County Medical Officer, Shire Hall, Durham, on or before the 22nd instant.
Shire Hall, Durham, January 5th, 1931. HAROLD JEVONS, Clerk of the County Council.

Liverpool County Borough.

LOCAL EDUCATION AUTHORITY.

JUNIOR ASSISTANT SCHOOL MEDICAL OFFICERS.

Applications are invited for Two Junior Assistant School Medical Officers at a salary in each case of £500 per annum, rising by annual increments of £25 to £700 per annum.
Applicants must be registered Medical Practitioners, and must have had at least three years' experience. It is desirable that they should have had some special experience in school hygiene and in diseases of children.
The officers appointed will be required to devote their whole time to the service of the Education Authority under the direction of the Medical Officer to the Education Authority. They will not be allowed to undertake private practice, and will be required to contribute to the Local Government and Other Officers Superannuation Act, 1922 (Substituted Scheme), as required by the Standing Orders of the City Council.
Form of application, which may be had by forwarding a stamped addressed foolscap envelope, should be returned, together with three copies of recent testimonials, to the undersigned not later than January 30th, and endorsed "Junior Assistant School Medical Officer."
The canvassing of Members of the Education Committee or the City Council is strictly prohibited and will be considered a disqualification.
Municipal Buildings, Liverpool. WALTER MOON, Town Clerk, and Clerk to the Local Education Authority.
January 13th, 1931.

Bradford Royal Infirmary.

Two HOUSE SURGEONS (male) wanted for March 1st.
Candidates must be single and legally qualified. Salary £150 per annum each, with board, residence, and washing.
There are 215 beds and six resident officers.
Applications, stating age, qualifications, and previous experience (if any), with copies of recent testimonials, to be received by the undersigned not later than Tuesday, Jan. 27th.
J. J. BARRON, Secretary-Supt.
January 11th, 1931.

City of Canterbury.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Council invite applications from duly registered Medical Practitioners of not more than 35 years of age, holding a Diploma in Public Health and possessing Municipal or Local Government experience, for the appointment of Medical Officer of Health and School Medical Officer.
The candidate appointed will be required to devote his whole time to the service of the Council, and must reside within the City.
The initial inclusive salary will be £800 per annum, rising by annual increments of £25 to a maximum of £900 per annum. An allowance of £40 per annum will be made in respect of the use of a car.
The appointment will be subject to the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.
The Council will provide offices and staff.
Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be sent (in envelopes endorsed "Medical Officer") so as to reach me not later than January 31st.
Fourteen copies of the application and testimonials should also be forwarded for the use of the members of the Public Health Committee.
Canvassing in any form is strictly prohibited and will disqualify.
R. H. WANKLYN, Town Clerk.
Town Clerk's Office, Municipal Buildings, Canterbury. January 7th, 1931.

Bedfordshire County Council.

ASSISTANT MEDICAL OFFICER (Resident)

Applications are invited for the appointment of a male Assistant Medical Officer (resident) at the BEDFORDSHIRE SANATORIUM, near Bedford.
The officer appointed will also be required to act as Assistant School Medical and Assistant Tuberculosis Officer in the County. The officer, who will be under the direction of the County Medical Officer of Health, will be required to perform such other duties as the Council may direct, and will be required to devote the whole of his time to the duties assigned to him, and not to engage in private practice.
Applicants must be under 35 years of age, single, registered Medical Practitioners, and have had experience in Tuberculosis work. Experience in School Medical Inspection, and the possession of a Diploma in Public Health, are desirable.
Salary £400 per annum, together with board, residence, laundry, garage, etc., and a travelling allowance of £150 per annum, the appointment to be subject to one month's notice to be given by either side at any date.
Further particulars can be obtained from the County Medical Officer, Shire Hall, Bedford.
Applications, stating age, qualifications, and previous experience, accompanied by copies of three recent testimonials, and endorsed "Assistant Medical Officer (resident)," should be sent to the undersigned not later than Jan. 22nd.
Shire Hall, Bedford. J. B. GRAHAM, Clerk of the County Council.
January 1st, 1931.

City of Leicester.

RESIDENT MEDICAL OFFICER.

JUNIOR [illegible] OFFICER (male) requit[illegible] HOS-PITAL AND [illegible] The appointment [illegible] twelve months. The [illegible]0 per annum, with board, residence, and laundry.
The officer appointed will be required to contribute to the Superannuation Fund of the Corporation.
Applications, stating age, experience, etc., together with copies of three testimonials, to be sent to the undersigned not later than Feb. 2nd.
C. KILLICK MILLARD, Medical Officer of Health.
Health Offices, Leicester.
January 12th, 1931.

(15 miles from Glasgow. 185 beds.)

RESIDENT MALE ASSISTANT MEDICAL OFFICER wanted.
Duties include charge of 90 beds for Epileptics as well as 75 beds for Consumptives.
The appointment will be for six months in the first instance, at the rate of £200 p.a., with board, laundry, etc.
Applications, stating age, qualifications, and previous experience, and enclosing copies of testimonials, should be addressed to E. J. PELL, Medical Superintendent, Sanatorium, Bridge of Weir, Renfrewshire.

Dudley Road Hospital.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital, Birmingham.

The Hospital accommodation is fixed at 926 beds, divided into Medical, Surgical, Children's Infectious, Maternity, Gynaecological, and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, Deep Therapy, X-ray, Electrical Massage, Sunlight, and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time for a further period not exceeding six months.

The persons appointed will be required to assist at operations, to administer anaesthetics, and undertake casualty work and such other duties as may be assigned to them by the Medical Superintendent.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

The officer appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

Further particulars of the appointments may be obtained from the Medical Superintendent, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital, Birmingham, to whom applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Thursday, January 22nd.

AMENORRHEA
DYSMENORRHEA

"It is a very great mistake to treat amenorrhea as though it were simply a lack of the catamenia, for it is a great deal more than that. Behind this lack lies a cause. It may be in the uterus or the ovaries, or it may be still farther back in the secretions of the endocrine glands or in the functioning of the vegetative nervous system."—("The Treatment of Amenorrhea," Dalché, *Revue Française de Gynecologie et d'Obstetrique*, May 1, 1920.)

In the treatment of irregularities of the catamenia, rational therapeutic procedure is directed to the restoration of normal balance in the endocrine and vegetative nervous systems.

Hormotone
BRAND

contains thyroid, pituitary, adrenal, and gonad substance, combined to take advantage of the demonstrated synergism existing between them. In the treatment of these disorders Hormotone has been very successful.

Dose: One or two tablets three times daily.

Overcomes Fear—

Nembutal '844'

a new and most efficient member of the barbituric acid series, has proved of outstanding value in overcoming pre-operative fear and apprehension, in assisting to maintain a satisfactory degree of hypnosis and freedom from pain during operation, and in diminishing the post-operative nausea, vomiting and pain which so commonly follow inhalation anaesthetics such as ether, etheline, etc.

Nembutal '844' [Sodium-ethyl- (1-methyl butyl) barbiturate] is one of over sixty barbiturates developed and studied in the Abbott research laboratories and clinically during the last thirteen years. **Nembutal '844'** possesses unusual properties as a pre-anaesthetic sedative and hypnotic. It is a quick-acting drug, having a short hypnotic but prolonged sedative action, from which recovery is remarkably rapid. The clinical use of **Nembutal '844'** is based upon extensive pharmacological investigation of many compounds, followed by clinical trial by physicians and a number of the largest clinics.

Nembutal '844' is valuable in surgery, in connection with general, local and spinal anaesthesia; in obstetrics, where its use has won the approval of the physician and patient alike; and as a quick-acting hypnotic to calm and control nervous, excited and demented individuals.

Nembutal '844' is employed pre-operatively by the oral route. The usual oral dose is one capsule (1½ grains) the evening before, and two capsules (3 grains) one hour before operation; when so used the amount of inhalation or other anaesthetic required is very markedly reduced.

Abbott's Nembutal '844' is supplied in bottles of 100, 1½-grain capsules, for oral use, and in boxes of six ampoules, each containing 7½ grains (0.5 gram) powder for use in preparing solutions for intravenous use; to control convulsions; or for rectal administration.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,500 copies.

J. & A. CHURCHILL

Purchase now and secure full year's use

87th Annual Issue. 2,400 pages. 55,000 names. 36s., postage 1s.

The MEDICAL DIRECTORY, 1931

Including Guide to British Spas and Marine Health Resorts, with 14 Pictures of Spas, etc. Edited by R. FORTESCUE FOX, M.D.

"This year, its eighty-seventh annual issue, the Medical Directory contains 2,263 pages, and the names of 55,035 practitioners. It is a volume for which one somehow feels affection, as well as admiration, because of its freedom from mistakes and misprints. The Medical Directory is indispensable and inimitable—an "unofficial" publication to which official publications must give pride of place."
—PRACTITIONER, Jan., 1931.

6 Illustrations. 3s. 6d. Postage 3d.

CHILL: ITS DANGERS AND PREVENTION

By MARIAN THORNETT, F.R.C.S.I.

DR. JANE WALKER says:—*"Dr. Thornett has produced scientific reasons for the reforms she urges. . . . Now we must go a step further and fight a campaign for the greater comfort and health of children. . . . Dr. Thornett has made a real contribution to national health, and especially to the health and comfort of young people and children. Her book should be very widely read."*

NATURAL APERIENT MINERAL WATER

OF

RUBINAT LLORACH

(Hydragogue, Purgative, and Cholagogue.)

The official analysis shows in each litre about 1601.321 grains of Anhydrous Salts, of which are Sulp. Soda 1485.368 grains, and Sulp. Magnesia 50.301 grains.

Prescribed in cases of Gall-stones, Liver Disease, and threatened Appendicitis, Constipation associated with Gout, Hepatic Dyspepsia, Gastric Fever, and generally in Abdominal Obstruction.

DOSE.

Wineglassful fasting; can be increased according to temperament. Effect is more rapid if followed by a cup of hot tea.

NO GASTRIC IRRITATION. NO ALTERATION IN DIET REQUIRED.

"A moderately powerful stimulant of the liver, and a powerful stimulant of the intestine."

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

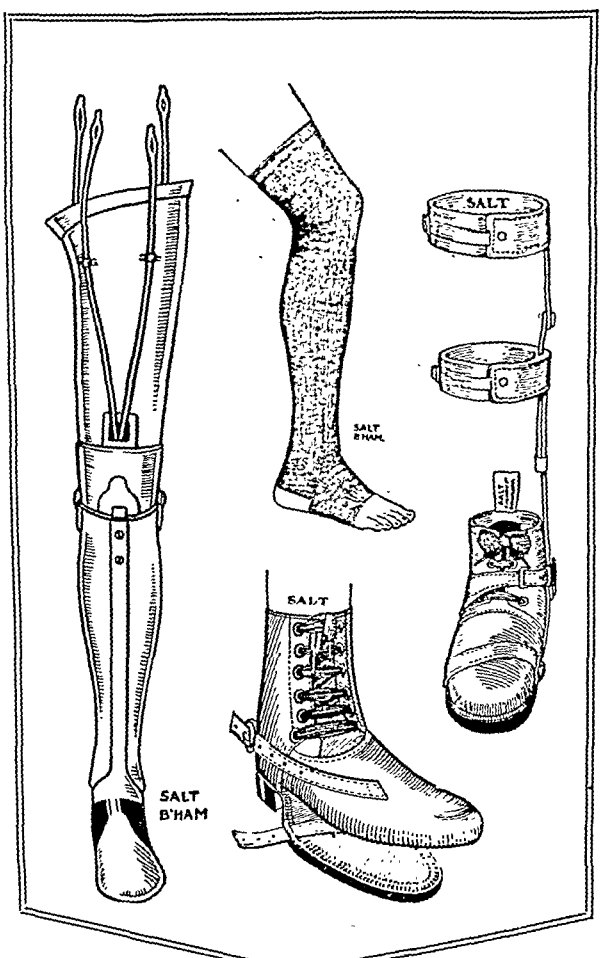
SURGICAL SERVICE
SALTAIR

SALT

SPECIALISATION
IN SERVICE

SALT



THE outstanding feature of Saltair Surgical Service is the fact that every appliance is specially made for each individual requirement, as prescribed by the attendant practitioner.

The majority of our appliances are our own patents and are registered patterns. New types are constantly being added, and we cordially invite the Medical Profession to co-operate with us in experimenting in new designs—at **OUR expense.**

All correspondence (excepting regarding London appointments) should be addressed to Birmingham.

'Phone (Birmingham): Midland 5455.

SALT AND SON LTD.

COPYRIGHT.

SERVICE IN SPECIALISATION

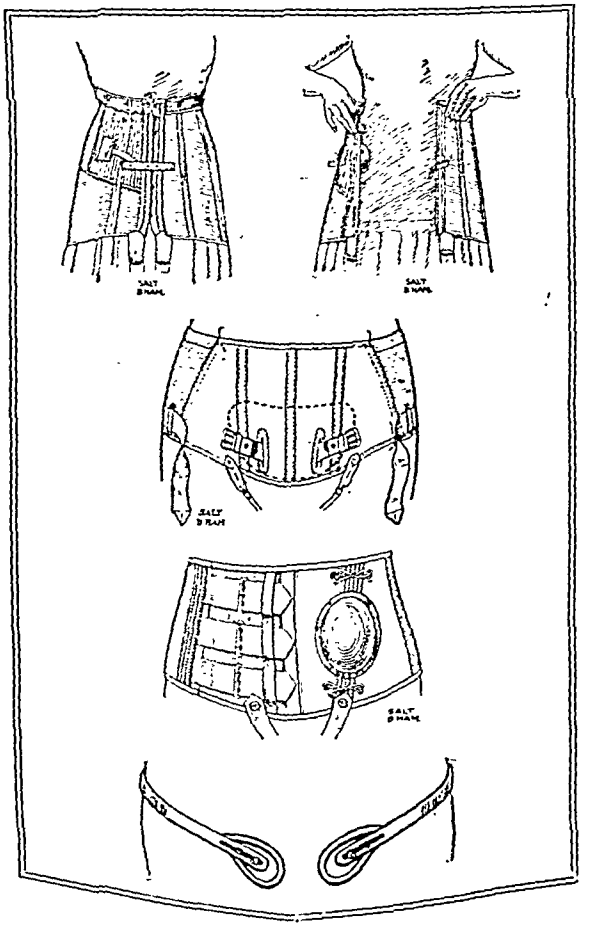
Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

OUR close co-operation with the Medical Profession for 138 years, together with our practical knowledge, enables us to interpret Medical requirements with the greatest accuracy.

Our Service—owing to our Depots and Fitting Rooms situate in London and provincial centres—enables the attendant practitioner to send his patient to be fitted by surgical experts with the exact type of appliance prescribed.



London Consulting Rooms:
"OAKLEY HOUSE," 14-18, Bloomsbury Street, W.C.1.

ONE DOCTOR AFTER ANOTHER PRAISES SPHAGNOL

"In a case of Psoriasis of the Scalp from which the patient had been suffering for 15 years, the use of Sphagnol Soap and Ointment for about two months has cured it."

"I have used your Sphagnol Soap and Ointment in a case of Seborrhoea and Acne with splendid results."

"Sphagnol has been used on one of the most distressing cases of Haemorrhoids and has acted like magic."

"I am constantly recommending Sphagnol Ointment just now for Insect Bites. It gives instant relief and brings out the inflammation in a remarkably quick way."

PEAT PRODUCTS (SPHAGNOL) LIMITED (DEPT. B 43), 21, BUSH LANE, LONDON, E.C.4.

Full-size trial package free to Medical Practitioners in the British Isles on application to Boots the Chemists, Station Street, Nottingham.

OLIVITA

OLIVE OIL WITH VITAMIN D

Olivita consists of the finest Virgin Olive Oil to which has been added that proportion of Irradiated Ergosterol which gives it a Vitamin D content equivalent to that of Cod Liver Oil.
Having investigated the conditions under which Boots Olive Oil is produced in Spain, the finest grade of Olive Oil available is guaranteed to be the first pressings from the Olives.
Olivita will be found very palatable and can be recommended without hesitation to regular users of Olive Oil.
The wide range of usefulness of Olive Oil is well known, and members of the medical profession will readily appreciate the [illegible] conferred on this product by the incorporat[illegible]
Recent researches have indicated that [illegible] D should form part of the diet of all children during the period while the permanent teeth are being calcified. Cod Liver Oil is now often given to babies as a regular part of their diet as a good source of Vitamin D and Olivita provides a palatable alternative.
Its keeping properties have been thoroughly tested.

Iodine-Medol

Non-Toxic, Non-Eschorotic, Non-Staining

IODINE-MEDOL, an antiseptic unguentum presenting Iodine in a form that actually penetrates the tissues and destroys the bacteria *in situ*. Case reports have shown this *Antiseptic Unguentum* to be of marked value in the treatment of skin troubles of a parasitical nature such as Impetigo, Scabies, Tynea Sycosis, etc. Owing to its special emusifiable base, Iodine-Medol is rapidly absorbed with deep penetration. To be used in all cases where Iodine medication is indicated.

Testing samples and full particulars sent on application to :—

Pearson's Antiseptic Co., Ltd., 61, Mark Lane, London, E.C.3.

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905)

Local Anæsthesia in Surgical Practice

UTERINE PROLAPSE.

Typical Case.

Mrs. E. D. F., aged 53.

Diagnosis: Uterine prolapse, third degree, with large vesicocele.

Operation: Watkin's interposition; perineorrhaphy.

Anaesthesia: Classical infiltration block, using 45 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution in perineum. A circumferential block about the cervix was made, using 30 c.c. of the same solution. The patient noticed some distress during delivery of the uterus into the vagina. The round ligaments were blocked as soon as they appeared, 4 c.c. of Novocain-Adrenaline solution being used in each case. The classical Watkin's operation was performed. The perineum was then repaired by the split septum method. Anaesthesia was ideal. Patient's pulse was 80 at the end of operation, and she had no post-operative nausea, vomiting, or gas pains, and made an uneventful recovery.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

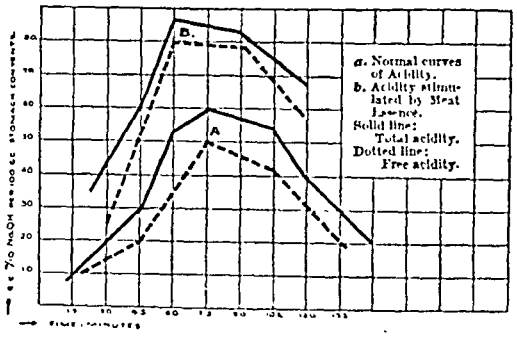
PERIOD OF DIGESTION REDUCED 29%

when these essences are taken

ONLY one hour and twenty-eight minutes are needed for the complete assimilation of meat essences by the digestive organs, as shown by recent scientific tests.

This is a saving of 40 minutes or 29% on the normal time taken for digestion. The flow of gastric juice is promoted to such an extent that 87% of the total acidity content of the stomach is reached in 37½ minutes. So quick is the absorption of energy thus induced by the stimulation of the gastric secretions, that the work of the digestive tract is reduced to a minimum and no solid residue is left. The nourishment needed to restore expended energy is supplied without effort or strain to the weakest system.

Made by an exclusive process which conserves the pure strength of the finest, freshly-killed English meats, Brand's



The increased rapidity of digestion when essences are taken is shown by this chart

* * *

Essences are absolutely free from preservatives and colouring matter. They are easy to swallow and delicious to taste. Patients relish them even in the most severe crises of illness.

Hundreds of doctors report on their unparalleled value—more particularly in cases of cancer, gastro-enteric catarrh and bowel trouble. Samples of Brand's Essences will be sent on receipt of a professional card.

A PINCH OF SNUFF

during the INFLUENZA SEASON

taken before and after examination of pulmonary cases is suggested to the Medical Profession as

THE BEST PREVENTION

to invasion by infecting germs in the nose and naso-pharynx.

DIMOL SNUFF

LABORATORY TESTS: Dimol Snuff has a coefficient equivalent to 30% pure phenol—that is, it is as active as a bactericide as pure phenol diluted with twice its volume of water—a strength of phenol of course quite intolerable in the respiratory tract.

Dimol Snuff diluted with 10 times its bulk of mucus will kill:

Pneumococci in 30 seconds
B. influenzae in 30 seconds
M. catarrhalis in 35 seconds
Streptococci in 40 seconds

Prices and particulars will be sent on application to

DIMOL LABORATORIES, LTD., 40, LUDGATE HILL, LONDON, E.C.4.

Why the profession approves Mistol

FOR a number of years leading rhino-laryngologists have been recommending an oily spray solution containing menthol, camphor, eucalyptol and chlorbutol, for common cold, chronic rhinitis, hay fever, minor sore throats and lesser inflammations of the upper respiratory passages.

The makers of Nujol developed this suggestion so as to produce, after much scientific investigation, a product containing these ingredients in the form best suited for intranasal medication. Mistol was the result.

Administered with the dropper contained in each package, Mistol immediately spreads evenly over the nasal mucosa so as to form a thin protective film. It has the further property of clinging tenaciously, so as not to be dislodged by secretions. Further advantages of Mistol are that it may be taken as a gargle or nebulized into a fine vapour for inhalation.

Because its use is based on sound medical practice, Mistol enjoys the highest measure of professional approval and confidence.

Mistol

OVALTINE

FOR THE GROWING CHILD

"Ovaltine" is indicated as a means of promoting normal growth and development when the weight of the child under observation is less than that which statistics show a child of the same height should weigh.

The physician has only to consider the composition and properties of the product to recognize how suitable it is as a building and reconstructive nutrient.

"Ovaltine" is a concentrated extraction of malt, milk, and eggs in the form of golden brown granules. For tissue growth or repair it provides proteins, mineral constituents, adequate energy value, and the Accessory Growth Factors or Vitamins in correct nutritive ratio.

Children love the deliciousness of "Ovaltine" and thrive remarkably well upon this complete food. It is of unsurpassable value as a meal-time beverage in place of tea, coffee, cocoa, or other beverages.

A liberal supply for clinical trial sent free on request.

Pneumococcus Antibody Solution

because

It is a specific treatment for the lobar pneumonias caused by Types I, II, or III pneumococcus. It has been subjected to a thorough clinical trial over a period of six years in both hospital and private practice.

It has been used on about 2,000 patients in private practice. Published reports cover nearly 1,000 cases.

When used early (on or before the third day), a definite shortening in the duration of the disease and a reduction of 50 per cent. in the mortality rate has been reported.

Serum sickness and anaphylaxis have not been observed in any instance.

It contains the pneumococcus protective antibody in the purest form generally available.

Typing, as a preliminary procedure, is unnecessary and causes delay. Experience has shown that the most benefit is derived from very early treatment. The dangerous bacteriemia accompanying many cases of pneumonia can often be controlled by this agent, especially in Type I cases. Intravenous administration is the preferred method, because the antibodies are thus made immediately available in the blood stream.

Thermal reactions, while they sometimes occur, are controllable by usual methods.

furunculosis

STAPHYLOCOCCUS Antivirus, prepared by the GLAXO LABORATORIES, is specific in the treatment of this and other suppurative lesions caused by staphylococcal infections, and will clear up the condition when all ordinary methods of treatment have failed.

Staphylococcus antivirus is a sterile detoxicated filtrate of a bouillon culture of a great variety of strains of S. Aureus and S. Albus. It is applied locally to the surface of the skin, or packed into the cavity on strips of gauze. Where a cavity exists with drainage to the surface the fluid may be used as an irrigation. The treatment is completely safe, and no general reaction is experienced. The method is much more rapid than antiseptic treatment, and instead of injuring the cells increases their resistance to infection.

The following typical cases indicate the clinical results that attend the application of ANTIVIRUS THERAPY, even to severe lesions of considerable duration:—

"The patient had had boils in the external auditory meatus for 7 weeks, accompanied by great pain, causing insomnia. Various methods of treatment had been adopted with no success. At 9.30 a.m. a dressing of staphylococcus antivirus was applied. At 4 p.m. the pain was relieved. On the third day of treatment the boils had cleared up and there has been no return."

"A dressing of staphylococcus antivirus was applied to a large, very painful and tender furuncle of the neck. In 24 hours the furuncle had burst; it was plugged with staphylococcus antivirus and in 5 days, dressings having been applied 12-hourly, was completely healed."

To these cases could be added many others showing the value of staphylococcus antivirus in the treatment of such conditions as suppurating wounds, post-operative sinuses and osteomyelitis.

The manufacturers will gladly co-operate with any physician . . . and surgeon . . . who cares to make further clinical trials by placing free supplies of staphylococcus antivirus at their disposal.

5 c.c. ampoules; box of six ampoules - - 5/- per bottle

(*Æsculapius*)

LIVER THERAPY IN PERNICIOUS ANAEMIA

The production of a palatable liquid preparation which conserves the potency of the fresh gland has proved a boon to medical men who wish to prescribe liver for fastidious patients.

HEPATEX

A highly concentrated extract is now accepted as a reliable means of obtaining the effects upon the blood picture, etc., which follow the administration of fresh liver. The erythrocyte count is rapidly raised to a satisfactory level, pallor disappears, and nervous symptoms show appreciable improvement. A reduced dosage then suffices to maintain a sense of well-being and to guard against relapse.

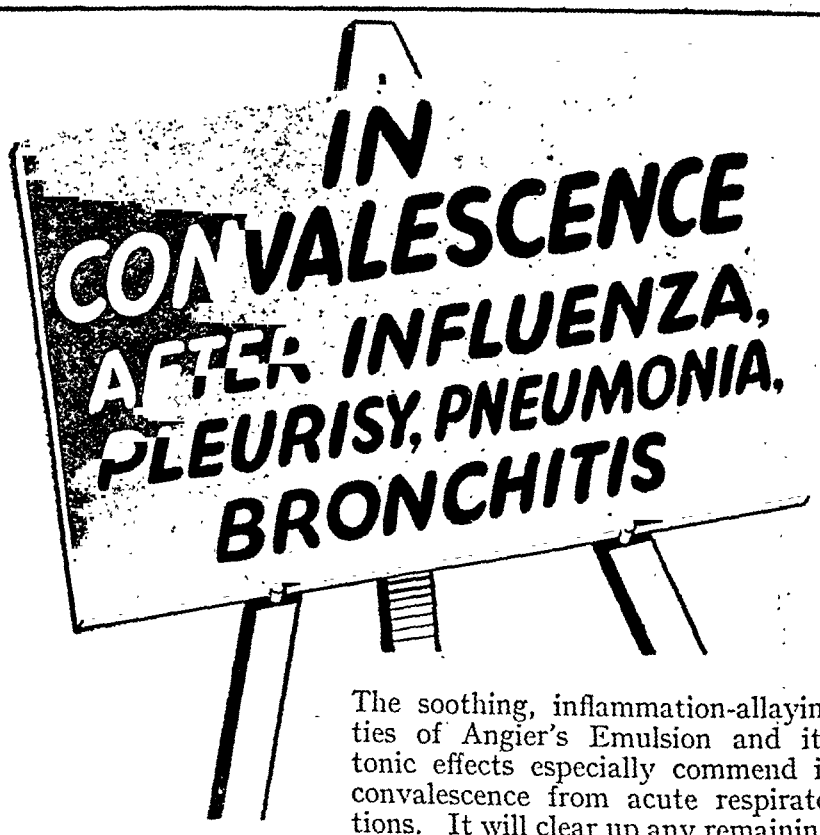
HEPATEX is concentrated so that one ounce represents the activity of one pound of fresh liver.

Issued in 4-oz. bottles at 12/6 a bottle.
Each bottle contains sufficient for
8 days' full treatment.

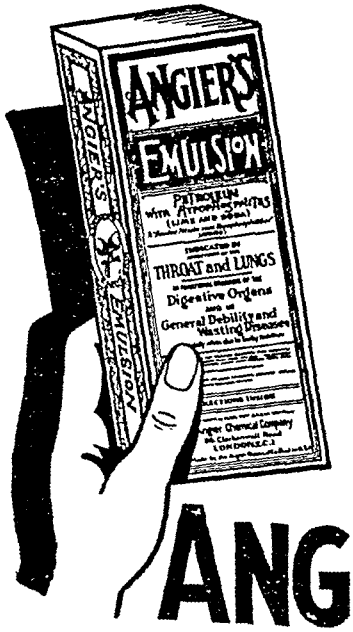
Prepared at
Evans' Biological Institute,
Higher Runcorn, Cheshire.

EVANS SONS LESCHER & WEBB Ltd

LIVERPOOL 56 Hanover St. DUBLIN LONDON 50 Bartholomew Close



The soothing, inflammation-allaying properties of Angier's Emulsion and its general tonic effects especially commend its use in convalescence from acute respiratory affections. It will clear up any remaining catarrh, whether of the respiratory or digestive organs. It will restore tone to the digestive functions, and greatly improve assimilation and nutrition.



An absolutely perfect emulsion, it is presented in a form pleasing to the taste, and acceptable to the most fastidious. Moreover, it can be administered to advantage in conjunction with other remedies, such as salol, aspirin, bismuth, etc.

Angier's Emulsion is made with petroleum specially purified for internal use. It is the original petroleum emulsion—the result of many years of careful research and experiment.

AND

N. HAMILTON FAIRLEY, O.B.E., M.D., F.R.C.P.

ASSISTANT PHYSICIAN AND DIRECTOR OF PATHOLOGY, HOSPITAL FOR TROPICAL DISEASES; LECTURER IN APPLIED PATHOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

Since the introduction of the rhesus monkey in the study of yellow fever by the American Commission in West Africa, various laboratory workers have acquired the disease, not through the agency of infected mosquitos, but by direct contamination with infective blood or tissues. Hindle, in a recent communication (1930), briefly referred to certain patients contracting the disease in this manner, but since the present outbreak, which started in July, 1930, involved, in addition, two of our hospital laboratory workers who had had no access to infected monkeys, we propose to give a more detailed account of the mode of infection. So important an experience justifies publication, as it forcibly illustrates the grave risk attending the routine collection and examination of human blood during the first four days in yellow fever cases.

Our first patient was a laboratory assistant from the Wellcome Bureau of Scientific Research, where experimental investigations on yellow fever were being undertaken. Infection occurred with a Brazilian strain which had been maintained by Dr. Hindle in monkeys and mosquitos for at least a year. At the time of contracting the disease, however, the only source of virus was *Macacus rhesus*.

CASE I

This patient, who was a delicate youth, aged 17, had never been abroad; he gave a history of measles, pertussis, and varicella in childhood, of suppurative appendicitis in 1923, and of an operation for right strangulated inguinal hernia in 1929. A mild attack of pneumonia occurred in the same year.

July 8th, 1930.—At 6.30 p.m. the patient, who was then quite well, went for a ride on his bicycle; about 10 p.m. he developed a headache, and later felt chilly, then hot.

July 9th.—The headache persisted, but he came to the laboratory in the morning. Half an hour after arrival he vomited bile, and repeated this forty-five minutes later. He returned home from work at 6 p.m.; was very restless that night, and vomited food once.

July 10th.—At 2.30 p.m. he was admitted to the Hospital for Tropical Diseases complaining of headache and fever. He sweated profusely, and at 6 p.m. the temperature was 104.8° F., the pulse was 100, and the respirations 24 per minute. The tongue was coated with fur, the face slightly flushed, and the conjunctival vessels were injected. No icteric tinge was present. The pulse was regular and bounding, and there was a blowing systolic bruit at the apex. The liver and spleen, though not enlarged, were definitely tender on deep palpation under the costal margin. The abdomen showed the scarred incisions of previous operations, but did not present any other features of clinical interest. That night the patient slept at intervals, the headache having abated somewhat by 10 p.m.

July 11th.—In the morning he was rather drowsy, and complained of photophobia. The tongue was dry, with yellowish fur laterally and a reddened centre. Herpes was present on the lower lip, and the eyes were definitely bloodshot. At 10 a.m the temperature was 102.2° and the pulse 88 per minute. At 2 p.m. blood was taken for biochemical estimations of urea and bilirubin, and some was also sent to the Wellcome Bureau of Scientific Research for inoculation into a monkey (*Macacus rhesus*). The specimen was collected sixty-four hours after the onset of the illness as judged by the initial headache. At 8.30 p.m. 12 c.cm. of immune serum were injected subcutaneously into the abdominal wall. This was obtained from a person who was known to have contracted yellow fever some months previously, and whose blood had been proved to be protective to animals inoculated with the virus. The urine (specific gravity 1012) was acid in reaction, and contained only a slight trace of albumin; bile salts and pigments were absent. The total quantity passed that day was 42 oz. The van den Bergh test yielded a negative direct reaction, and an indirect reaction of only 0.8 unit. The blood urea figure was 46 mg. per 100 c.cm. Haematological estimation showed that the red blood corpuscles numbered 4,400,000 per c.mm., the haemoglobin percentage was 80, and the colour index 0.9. The leucocyte count was 9,000 per c.mm.

July 12th.—The patient had slept during the night, but now again complained of photophobia. The pulse was 80 per minute, regular, and slow compared with the temperature (102°). No vomiting, rash, or jaundice was present, but the conjunctival vessels were congested. Slight twitchings of the arms and face were noted. The urine still contained only a trace of albumin, and 40 oz. were passed in the twenty-four hours. During the evening the patient was drowsy and slept at intervals, at 10 p.m. a loose stool containing mucus was passed.

July 13th.—The patient appeared somewhat weaker, the temperature was 102°, and the pulse still slowing—74 per minute. A distinct trace of jaundice was evident on the conjunctivae. The urine was acid, with a specific gravity of 1022, and the amount of albumin had increased. The total quantity passed in the twenty-four hours was 38 oz. Urobilin was present, but there were no bile salts or pigments. Vomiting occurred during the day, and indigestion was complained of at 10 p.m., but the patient slept satisfactorily despite it.

July 14th.—During the morning the breathing was somewhat irregular, and at times slight cyanosis developed. There was a good deal of muscular twitching, and the patient complained of abdominal pain. Vomiting occurred only once. The blood pressure was then: systolic 110, diastolic 66. The urine contained a considerable amount of albumin (0.3 per cent.), and also urobilin; the total amount passed in the twenty-four hours was 46 oz.

July 15th.—At 2 a.m. the temperature fell to 98.8°; subsequently during the day it rose and fell thrice. The patient was restless, troubled with nausea and abdominal pain, and vomited once. A saline enema was given at 6 p.m., with good result. The urine was acid, and contained a considerable quantity of albumin (0.5 per cent.); bile pigment in small quantity was present, and there was a marked excess of urobilin. The total quantity passed in the twenty-four hours was 36 oz.

July 16th.—The patient now remained afebrile, the general condition improving, and the tongue being moist for the first time. The urinary findings were almost identical with those recorded on the preceding day (albumin 0.45 per cent.), but microscopical examination showed granular casts and a few leucocytes. The van den Bergh test showed a negative direct reaction, the indirect registering 1.2 units.

July 17th.—No further rises of temperature were recorded, but the tendency to sweating was marked. The urine still contained a trace of bile pigments, much urobilin, and considerable quantities of albumin (0.4 per cent.). The blood urea figure was 29 mg. per 100 c.cm.

July 19th.—The patient's condition was quite satisfactory, and the urine now contained only a trace of urobilin and albumin (less than 0.01 per cent.).

July 20th.—The patient was discharged from hospital. Convalescence was uneventful, and two months later normal health was attained.

Commentary

In addition to convalescent serum the patient was given 10 grains of calcium lactate three times daily, and glucose in his drinks. For the first few days plain water, albumin water, and diluted milk were alone allowed, and later Horlick's malted milk and peptonized milk. As much fluid as the patient could swallow was administered, the nursing staff being instructed to see that at least 80 oz. of fluid were taken

daily. Symptomatic treatment was instituted when necessary; an ice-bag proved useful for headache, glycerin suppositories and saline enemata for constipation, and sponging for reducing the temperature. On July 21st sago, eggs, and junket were permitted, and later toast, butter, pounded fish, and weak tea were added to the menu. A full diet was allowed ten days later.

This case ran a typical course of a moderate infection of yellow fever, the pyrexial bout lasting seven days, with bradycardia as a marked feature of the illness (see chart). Albumin appeared in the urine on the third day, and bile pigment on the seventh day of fever, though an icteroid tinge of the skin and conjunctivae was noted on the fifth day.

The low blood urea and the low van den Bergh findings are of special interest when compared with those found in blackwater fever, where much higher values are recorded.

CASE II

The second patient, aged 28, first examined the blood of the preceding case on July 11th, 1930. The specimen was sent from the ward to the laboratory with the request for an estimation of bilirubin and urea. Blood collected at the same time was inoculated subcutaneously into a monkey of the species *Macacus rhesus* at the Wellcome Bureau, the animal succumbing subsequently to yellow fever. The only other occasion on which the second patient could have come into contact with yellow fever was on July 16th—five days later—when the biochemical tests were repeated. By this time, however, the blood was non-infective, so that the date of exposure in this case can be definitely fixed.

July 21st, 1930.—The patient was quite well during the day, then suddenly, about 10 p.m., he was taken ill with generalized headache. Shivering started about 11 p.m., and severe abdominal pain and discomfort followed. Flatus was passed with difficulty. The condition was as if "lumps of ice were located in the abdomen." Castor oil taken in the early morning brought some relief.

July 22nd.—Next morning he was seen by Dr. W. Williams, the temperature at 8 a.m. being 100.2°. The general condition remained much the same, the fever, headache, nausea, and other features persisting. In the afternoon the temperature was 100.8°, while at 8 p.m. it was 102°.

July 23rd.—Next morning at 10 a.m. the temperature was 102°, and at 5 p.m. 102.6°. Dr. Williams then got in touch with one of us (G. C. L.), who arranged for admission to the Tropical Diseases Hospital. The patient was by this time complaining of very severe supra-orbital headache, fleeting pains in the muscles, and pain in the lumbar region. The face was flushed, and there was some visible perspiration. No obvious anaemia or jaundice was present; the tongue was thickly covered with white fur. The temperature was 102.6°, and the respirations 18 per minute. The pulse, which was 72 per minute, was regular in time and force, and of good volume; the blood pressure was sustained, the systolic pressure being 126 and the diastolic 62. No abnormal physical signs were detected on examination of the heart or lungs. The abdomen was slightly distended and the parietal muscles were somewhat rigid, but no visceral enlargement or localized tenderness was elicited on palpation. The urine contained both albumin and phosphates.

July 24th.—In the morning the temperature was 103°, and the general condition unchanged. The pulse was now only 60 per minute; this bradycardia subsequently persisted throughout the pyrexial period. Blood was collected from the ear by a laboratory technician, who later developed the disease (Case III) The red blood corpuscles numbered 5,000,000 per c.mm., the haemoglobin percentage was 90, and the total leucocyte count was 5,000 per c.mm. The differential count revealed 81 per cent. of neutrophil polymorphs, and 19 per cent. of lymphocytes. The urine had a specific gravity of 1025, was acid in reaction, and contained a quantity of albumin and urobilin, but no sugar, bile salts, or acetone bodies. During the day the patient slept on and off, but still complained of headache, and was at times restless. About 11.30 p.m. 30 c.cm. of convalescent serum from the first case was injected subcutaneously, and calcium lactate and glucose were commenced, the patient being treated along the lines already indicated in Case I.

July 25th.—At 6.15 a.m. the patient vomited, but later the headache improved somewhat, and the temperature tended to fall. The pulse kept at about 60 per minute thoughout the day. At 3.15 p.m., 89¼ hours after the onset of the illness, blood was taken for inoculation into a monkey, which subsequently died of yellow fever, necropsy revealing the typical pathological changes. The van den Bergh test showed a delayed direct reaction and an indirect reaction of 1.5 units of bilirubin (0.75 mg. per 100 c.cm.). At 9.30 p.m. the patient complained of pain in the lower abdomen, associated with a desire, but an inability, to micturate.

July 26th.—Hot fomentations failed to give relief, and at 1 a.m. 48 oz. of urine were withdrawn by catheter. Next morning the general condition had markedly improved; the temperature fell to 97°, but rose subsequently to 100°; the pulse remained slow, and the tongue somewhat dry, furred, and dirty. The urine still contained albumin in quantity, but no bile salts. Urobilin was present, and the Rothera test, though not Gerhardt's, was positive. At 6 p.m. he was again catheterized, 31 oz. of urine being withdrawn.

July 27th.—The secondary rise in the temperature chart, so characteristic of yellow fever, now occurred (see chart). The pulse remained slow, and did not appreciably increase with the subsequent rises in temperature (Faget's sign); generally the rate varied between 50 and 65 beats per minute. The blood pressure was still well maintained, the systolic being 115 and the diastolic 70, while the urinary findings were similar to those seen on July 26th. The conjunctival vessels were somewhat injected, and an icteroid tinge of the skin was present. During the day he complained of headache, and slept on and off. He passed 20 oz. of urine with difficulty at 10 p.m., and after that slept well from 11 p.m. to 6.30 a.m.

July 28th.—The jaundice now appeared less, but abdominal discomfort persisted, necessitating hot fomentations. During the day the temperature varied from 100° to 101.4°, and the pulse from 60 to 65 beats per minute. The respirations remained stationary at 20 per minute. The patient slept from 9.30 p.m. to midnight, and then complained of inability to micturate. After hot fomentations 20 oz. of urine were passed.

July 29th.—The eyes were still very injected, the face looked flushed, and the patient complained of headache. Throughout the day the temperature varied between 99.2° and 101.6°, and the pulse between 58 and 64 per minute. The respirations remained unaltered at 20 per minute. The urine showed a fair amount of both albumin and urobilin, but no bile.

July 30th.—The patient passed 18 oz. of urine during the morning, but only after hot fomentations had been applied to the hypogastrium. A delayed direct van den Bergh reaction and an indirect reaction of 2.5 units were recorded. Clinically, jaundice was now more evident than at any previous time. The urine showed albumin and bile pigments, but not bile salts.

July 31st.—In the early hours of the morning the temperature fell to normal, varying from 97° to 98.4° throughout the day; the pulse remained slow, varying from 52 to 60 beats per minute. Albumin, urobilin, and bile pigments were still present in the urine, and next day bile salts were also detected. The subsequent course of the illness was uneventful, except that for the next five days rises of temperature of from 99° to 100.4° were noted. Bradycardia also persisted, the pulse remaining between 49 and 68 beats per minute. Throughout this period the tongue was somewhat furred, and on occasions there were attacks of headache, restlessness, and excessive perspiration.

August 5th.—The urine contained a trace of albumin, but no bile salts or pigment.

August 6th.—The diet was now reinforced with junket, chicken broth, and toast; later, eggs, sago pudding, and chicken were added to the menu. After this steady improvement followed.

August 23rd.—The patient was now transferred to a convalescent home, and later, after a month's holiday, he returned to duty in normal health.

Commentary

Points of interest in this particular case are the definite incubation period of ten days, and the proved persistence of virus for at least 89¼ hours in the circulating blood. The classical "saddle back" temperature and bradycardia are well illustrated in the accompanying chart.

CASE III

On July 24th, before the establishment of a definite diagnosis, a laboratory technician, aged 21, had performed a blood count on the second patient, and for this purpose had collected the blood himself. Until August 2nd he was at work as usual in the laboratory.

August 3rd, 1930.—At 2 a.m. he awoke with chill and sweating. Headache, backache, and epigastric pain soon developed, and rapidly became worse. He was admitted to the Hospital for Tropical Diseases at 11 a.m. that day, complaining of shivering, headache, and abdominal pain. The temperature was then 99.8°, the pulse 136, and the respirations 28 per minute. Shortly after admission he vomited a small quantity of bile-stained fluid speckled with brown.

Examination revealed a young man of good physical development, with a flushed face and slightly injected conjunctivae. He was very restless, the breathing was rapid and laboured, there was a dry cough, and occasional attempts at vomiting were evident. The skin was warm, dry, and not jaundiced. The tongue was dry and the throat congested. The pulse was full and bounding, its rate being 136 per minute; the systolic pressure was 120, and the diastolic 80. No abnormal physical signs were detected in the chest.

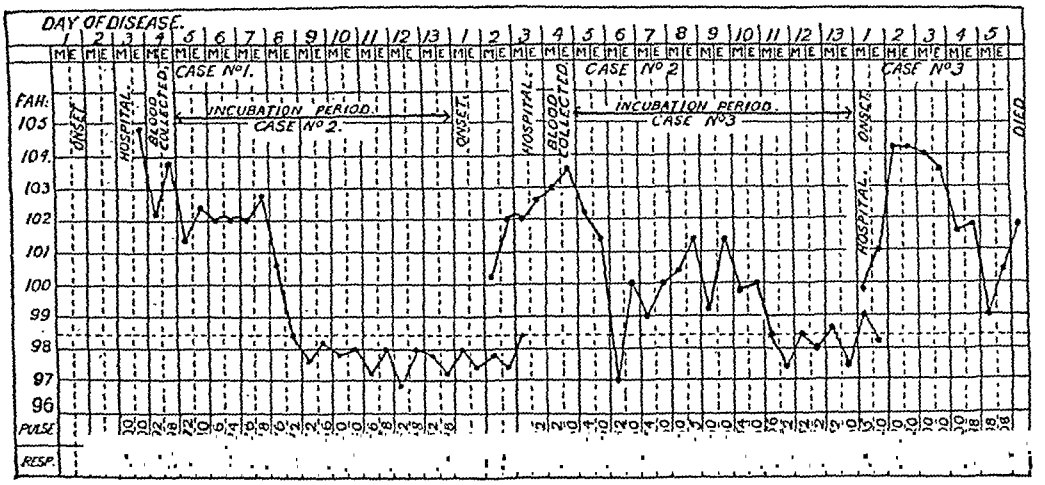
On examining the abdomen there was no rigidity, though tenderness was marked in the epigastrium, the right and left hypochondrium, and the flanks. The spleen was also tender and just palpable, but the liver showed no demonstrable enlargement. Active reflexes and photophobia were present. The urine was alkaline, and contained no albumin or bile; 16 oz. were passed soon after admission.

By 9 p.m. the headache was less severe, but the general condition remained unaltered. About 24 c.cm. of convalescent yellow fever serum from Case 1 was then administered subcutaneously, and 10 grains of calcium lactate three times a day was prescribed. The general line of treatment followed that outlined in the preceding cases, fluids and glucose being given freely. During the night the patient slept for short intervals, but restlessness was marked, the skin was hot and dry, and headache and painful micturition were present.

August 4th.—The tongue was dry, with central fur; the temperature was 104°, the pulse 120, and the respirations 26 per minute. The blood pressure was well sustained, the systolic being 124 and the diastolic 80. Urine was passed naturally, the specific gravity being 1022; there was an amphoteric reaction and a fair quantity of albumin. Urobilin was present, but not bile salts or pigment, sugar, or acetone bodies. The total quantity passed in the twenty-four hours was 34 oz. During the afternoon the patient again complained of headache, and appeared dazed, but he slept for short intervals. At 9 p.m. sighing, irregular respirations were first noted, and later incontinence of faeces developed, several loose stools being passed throughout the night.

August 5th.—In the morning the patient was obviously worse; he was very restless, at times delirious, and vomited a small amount of yellowish brown fluid. The temperature was 104°, the pulse 100, and the blood pressure had risen to 132 systolic and 96 diastolic. The face was flushed, the skin was definitely jaundiced, and the motions were loose and dark. Epistaxis occurred. During the day 54 oz. of urine were passed. Examination showed a specific gravity of 1016, slight acidity, and a moderate amount of albumin (25 mg. per cent.). Urobilin and a trace of bile salts were present, while the deposit contained numerous granular tube casts and epithelial cells.

August 6th.—There was no improvement, though the temperature was somewhat lower (102°). The patient was very restless and delirious, and vomited several times before 11 a.m. Retching was troublesome, and the typical "black vomit" now appeared. Yawning and sighing respirations also ensued, and later an attack of hiccups occurred, lasting one hour. The urine findings were similar to those on August 5th, except that pus cells appeared for the first time in the centrifugalized deposit. Again 54 oz. were passed in the twenty-four hours. By 5 p.m. the respirations became shallow, the pulse weaker, and rapid changes in colour were observed, the flushed, jaundiced face on occasions suddenly developing a sickly pallor. Oedema of the eyelids appeared later, and by 11 p.m. the patient lay curled up in bed, refused all nourishment, and at times was so restless that he was restrained only with difficulty.



Charts illustrating the incubation period in hospital infections with yellow fever.

August 7th.—During the early morning hours some sleep was obtained, but restlessness and delirium persisted; retching was troublesome; and the breathing was shallow, and often periodic in type. At 7 a.m. 25 oz. of urine were withdrawn. The temperature was now 99°, the pulse 88, and the respirations 28 per minute, while the blood pressure was 115 systolic and 80 diastolic. The tongue was dry and dirty, the lips cracked, and the breath foul. Puffiness around the eyes had decreased, but the skin was more jaundiced and at times somewhat cyanosed. The neck was stiff and the head retracted; the eyes were closed, and delirium was continuous. Twitchings of the facial muscles were also evident. The blood pressure was higher than in the morning, the systolic being 126 and the diastolic 80. Black vomit and melaena occurred during the afternoon, and later petechiae appeared on the skin of the back and face. At 6.30 p.m. the intense hiccupping, which had been continuous since midday, ceased, following injections of morphine and atropine and the application of a mustard plaster to the epigastrium. After this the patient slept for some time, but later grave toxaemic features developed. He now lay curled up in bed, with head retraction, half-closed eyes, and turned-up eyeballs. Epistaxis again occurred. The breathing was shallow and irregular, and sometimes periodic in type, the blood pressure fell (systolic 96 and diastolic 80), and the pulse became irregular, weak, and finally imperceptible. Digitaline, pituitrin, and intravenous glucose were given without benefit, and the patient succumbed at 4.5 a.m. on August 8th after less than five days' illness.

Commentary

This patient undoubtedly contracted his infection while either taking the blood or performing a blood count on Case II. The incubation period was ten days. From the onset he was severely ill, and the pulse, though slower than at first, failed to show the characteristic bradycardia met with in the other cases. There was no evidence that the convalescent serum administered on the first day of illness decreased the intensity of the toxaemia, or that calcium lactate had materially modified the tendency to haemorrhage, as Hindle and Findlay (1930) had found in experimentally infected monkeys.

General Discussion

Until 1928 investigations on yellow fever were invariably conducted in countries where it was endemic, and for this reason when members of the medical, laboratory, and nursing staff developed the disease, infection was attributed as a matter of course to the bite of the natural vector, *Aëdes argenteus* (*Stegomyia fasciata*). The tragic ends of Guillet, Adrian Stokes, Young, and Noguchi on the West Coast of Africa dramatically directed attention to the dangers of direct infection, while, as Hindle (1930) points out, the frequency of laboratory infections in Europe and America during the past two years has proved beyond all doubt the danger to man of direct virus transmission from contact with the blood of infected monkeys during life, or with their organs at necropsy. As a result of the death of Adrian Stokes, who had not been working with infected mosquitos for several months, Bauer and Hudson (1928) investigated the passage of virus through the skin of monkeys. They showed that yellow fever resulted if infected blood was merely rubbed on the normal intact skin of the abdomen of *Macacus rhesus*, but they stress the delicacy of the dermis in this situation, and point out that these experimental results did not determine whether the virus was capable of penetrating the normal unimpaired human skin of the hands, which is of thicker and denser texture. In the case of Adrian Stokes several abrasions were recorded as being present, but in our patients this was not so. Cases II and III illustrate the important fact that, in man, yellow fever virus is capable of penetrating the intact skin of the hands.

In countries where yellow fever is endemic it must frequently be necessary to take blood films, to make blood counts, and to perform routine tests of a similar nature on patients during the incubation period and febrile stages of this disease prior to its diagnosis. Our experience shows conclusively the very great danger associated with such procedures—at least during the first four days of fever. In the laboratory of the Hospital for Tropical Diseases antiseptic lotions were used for the hands, and all pipettes, syringes, and other glassware were unfailingly sterilized after coming into contact with infective blood, yet despite these precautions two of our staff were directly infected, as detailed in the text. Gloves, however, were not worn. This measure appears to be the only satisfactory one for preventing direct infection, for several others of us who employed gloves in collecting and handling infective blood did not acquire the disease. The virus content of human blood, during both the incubation period and the febrile stage, is not known as accurately as in monkeys, where it is recorded that 1 c.cm. of blood on the first day of fever commonly contains from one to ten million certainly lethal doses. Microscopic quantities of blood will probably infect, and our recent experience convinces us that in yellow fever countries many members of the medical, laboratory, and nursing staffs must in the past have acquired the disease in so simple a procedure as preparing blood slides, through not realizing its extraordinary infectivity and the capacity of the virus to penetrate unbroken skin.

The black vomitus, urine, and faeces from human sources are generally regarded as non-infective, and the organs at necropsy are held to be innocuous, owing to the disappearance of the virus by the time the patient succumbs. Davis and Burke (1929), however, infected a monkey from kidney tissue in a patient dying after three and a half days of fever, while in one of our cases human blood was proved to be infective 89¼ hours after the illness commenced. It should not be too lightly assumed, therefore, that post-mortem examination in man is entirely free from the risks of direct infection, and in all patients dying before the fifth day of the disease adequate precautions should be taken.

The subcutaneous administration of convalescent serum derived from patients who had recovered from yellow fever did not appear to modify the course of the disease in our patients. This was especially evident in Case III, death occurring after less than five days' illness, despite the injection of 24 c.cm. of convalescent serum within nineteen hours of the onset of the fever. Similarly, in Case II, though the patient recovered, the blood was found to be infective 89¼ hours after onset, despite the fact that serum had been injected 15¾ hours previously. In monkeys serum is of no therapeutic value once the disease is established, but Stokes, Bauer, and Hudson (1928) showed that as small a quantity as 0.1 c.cm. of immune serum would afford absolute protection for a monkey against subsequent inoculation with virus. Such findings suggest the advisability of immediate prophylactic inoculation whenever man has been exposed to contact with infected blood, while the long incubation period of ten days in the present series indicates the feasibility of this procedure.

Summary and Conclusions

1. Three cases of direct infection with a Brazilian strain of yellow fever are recorded in laboratory workers in London.

2. Two of these patients never came into contact, either directly or indirectly, with infected monkeys; they acquired the disease during routine hospital examinations, one in making blood slides and performing a white cell count, the other in doing routine biochemistry on a specimen of blood sent to the laboratory.

3. The incubation period in both cases was ten days.

4. Monkey inoculation showed that the blood of one case was infective for at least 89¼ hours after the onset of fever, despite the earlier injection of immune convalescent serum.

5. The hitherto little-appreciated danger of routine blood examination in cases of yellow fever during the first four days' illness, and probably also in the incubation period, is emphasized.

6. It is strongly urged that in endemic areas when yellow fever is prevalent gloves should invariably be worn when taking blood, whether the case is suspected of being yellow fever or not.

Our best thanks are due to the nursing staff of the hospital and to the resident medical officers, Dr. K. Lindsay and Dr. C. J. Hackett, for their tireless devotion to these cases during their illness.

MALIGNANT DISEASE OF THE LUNG*

BY

A. TUDOR EDWARDS, M.D., M.CH., F.R.C.S.

SURGEON, BROMPTON HOSPITAL; SENIOR SURGEON TO OUT-PATIENTS, WESTMINSTER HOSPITAL

(With Special Plate)

Malignant disease in the chest—and especially in the lung—has occupied the mind of the profession to a much greater degree during recent years than formerly. Whether there has been a definite increase in the incidence of malignant disease in the lung during the last ten or twelve years has been, and still is, much debated. Of one thing there appears to be no doubt: the incidence of cases diagnosed is much higher to-day than even as recently as five or six years ago.

Primary malignant neoplasms in the chest—and more especially those arising in the lungs—are extremely insidious in their onset, and may have been present for many months before their presence is suspected. Unfortunately in a large proportion of them dissemination into the glands of the mediastinum has resulted by the time the symptoms are sufficient to cause the patient to seek medical advice, and all hopes of successful surgical removal of the disease is gone. In the lung, carcinoma appears to arise primarily in two situations—the bronchi and the parenchyma. In the bronchi, carcinomatous changes may originate—

(1) in the epithelial lining of the tubes, comprising (*a*) the squamous-celled group which result from anaplasia or metaplasia of the normal epithelial lining cells, and (*b*) the so-called cylindrical-celled carcinoma in which there is very wide variation in structure; or

(2) in the mucous glands, in which growths—generally alveolar in structure—myxomatous degeneration is often seen.

In the lung parenchyma the histological appearances vary somewhat according to the type of tumour. In the diffuse pneumonic type, involving varying proportions from part of a lobe to the whole lung, the alveoli are occupied by masses of cuboidal, cylindrical, or flattened cells. The localized carcinomata in the parenchyma may be single or multiple, and consist of vesicles partially filled with papillary projections of cylindrical cells. Endothelioma of the lung has been described, the growth being localized to a greater or lesser degree, and consisting of masses of cells of endothelial type. These are sometimes confused with the squamous-celled carcinomas. Sarcoma is generally of the spindle-shaped type, and varies considerably in size, occasionally filling the hemithorax, eroding ribs and even chest wall. Sarcomata are much rarer than has been thought, and unquestionably a number of cases formerly described as sarcoma would now be classified as carcinoma.

SYMPTOMS AND SIGNS

The onset of malignant disease is generally very gradual and insidious, but in a number of cases is initiated by a pyrexial attack commonly labelled influenza. For weeks, and occasionally for months, the history in others may disclose nothing except increasing lassitude without localizing symptoms. This symptom is later accompanied by dyspnoea or non-productive cough, both persisting and tending to become worse. The general appearance is often good, and weight may even be gained at this period. Haemoptysis occasionally occurs early. Irregular pyrexia may be an early symptom, but the temperature is rarely high until the later stages, when there is retention of secretions, or when necrosis has occurred in the centre of the growth. A sudden attack of haemoptysis, associated with the expectoration of a quantity of purulent sputum, occurs occasionally in malignant disease, and tends to confuse the condition with pulmonary abscess, especially as it is often preceded by a rise, and succeeded by a fall, of temperature. Pain is certainly rare in the early stages, but until the pleura or mediastinum is involved is never severe. Dysphagia occasionally results from the pressure of secondary deposits in mediastinal glands upon the oesophagus, and hoarseness from pressure upon, or involvement of, the left recurrent laryngeal nerve.

The signs vary according to the type of the disease. In the bronchial growths the physical signs are those of pulmonary atelectasis, bronchial breathing of a blowing type, some dullness, and often increase of voice sounds when the obstruction is incomplete, with dullness and weakness or absence of breath and voice sounds when complete bronchial obstruction is present. In the central or alveolar type physical signs may be absent, or may consist of localized dullness associated with weakness of breath and voice sounds. Extrapulmonary signs should also be sought for, such as enlarged supraclavicular glands and paralysis of the homolateral diaphragm due to phrenic nerve involvement. Evidence of venous obstruction, such as dilatation of the superficial veins of the chest and the veins of upper limb and neck, is comparatively rare in pulmonary neoplasms. Effusions of the pleura are usually late in their incidence, and are often haemorrhagic. Bronchiectasis secondary to the obstruction results in a proportion of cases, and its symptoms may mask those of the initial lesion.

DIAGNOSIS

The fact that the signs are atypical of any of the common lung diseases should immediately suggest the possibility of malignant disease of the lung. Diagnosis may be confirmed by further investigations. These comprise *x*-ray examination, before and after pneumothorax, and the introduction of lipiodol into the bronchi, bronchoscopy, thoracoscopy, and, finally, exploration of the thoracic cavity.

X-ray Examination

This examination should consist of observation of the patient under the screen to judge the range of diaphragmatic movement and the manner in which the lighting up of the lung field varies during inspiration and expiration. The different types of pulmonary growth give rise to different radiological appearances.

(*a*) *Growths Obstructing the Bronchus.*—A characteristic appearance is given in skiagrams where a neoplasm is occluding a bronchus sufficiently to prevent the passage of air into and from the area of lung supplied by that bronchus. The air in the occluded portion of lung is gradually absorbed, and the lung tissue appears opaque in the skiagram. Generally the area is somewhat wedge-shaped, with the apex at the occluded bronchus and its base at the periphery. When the main bronchus to a lobe is occluded the whole lobe becomes atelectatic and shows a shadow. When the obstruction has been present for some time the mediastinum may be displaced to the affected side. *X*-ray examination, following the introduction of lipiodol, will often show an irregularity in the shadow of the opaque oil which has collected above the obstruction, corresponding to the irregularity at the surface of the growth. Naturally, the oil will not enter the obstructed part of the lung. Other causes of bronchial occlusion, such as foreign bodies, can generally be eliminated by the history, but where there is any doubt bronchoscopy should be performed.

(*b*) *Central Growths.*—In localized growths in the parenchyma of the lung the skiagrams show a definite opaque shadow corresponding in outline with the tumour. There is complete absence of any pulmonary reaction

*A paper read at the joint meeting of the Sections of Surgery and Tuberculosis at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

around, as is seen in infective conditions such as abscess, and this usually results in a very clear definition of the margins of the growth. Pleural and subpleural tumours often give similar appearances in skiagrams to those of central pulmonary neoplasms. Where pneumothorax is possible these can be differentiated, the lung collapsing partially over the intrapulmonary growths, whereas extrapulmonary growths can be seen outside the area of the collapsed lung. In a certain proportion of cases the centre of the growth necroses, and should infection spread in from the bronchi an infective abscess surrounded by new growth will result, whereon the *x*-ray appearances will be altered and the opacity be much more diffuse and ill-defined owing to the inflammatory reaction in the surrounding lung. This complication accounts for those cases of new growth which are diagnosed as pulmonary abscess and treated as such for some time before the underlying cause is suspected.

Bronchoscopy

In all cases in which there is evidence of bronchial obstruction, bronchoscopy should be undertaken. Not only these cases, but those of patients in whom haemoptysis is a prominent symptom and in whose sputum no specific organisms, such as tubercle bacilli, can be found after several examinations, should be submitted to bronchoscopy. During this examination it is often found difficult to distinguish a malignant growth from oedematous granulation tissue, and it is therefore essential that a small portion of suspicious tissue should be removed for histological examination.

Thoracoscopy

Following the production of an artificial pneumothorax or the replacement of an effusion, either haemorrhagic or serous, by air, thoracoscopy may be of value in a limited number of cases. In cases where the growth or growths are superficial in the lung it may enable a definite diagnosis to be made. It may also be of value in the differentiation of growths of the lung itself from growths of the pleura or chest wall.

Thoracic Exploration

It cannot be questioned that the enormous advance made in diagnosis and treatment of abdominal disease in the past is largely due to the frequency of exploration for obscure lesions. In our comparative ignorance of the early pathology of chest disease it is surely reasonable to expect that exploratory thoracotomy should be much more frequently undertaken than is the case if progress is to be made. Exploratory thoracotomy as carried out under modern conditions and, if possible, preceded by the induction of artificial pneumothorax, is certainly no more serious a procedure than abdominal exploration, and in general the patients have much less post-operative discomfort. Intercostal incision, with retraction of the adjoining ribs, gives sufficient exposure, and rib resection is unnecessary, except in older subjects in whom the costal cartilages are ossified. In each of two cases of suspected malignant disease submitted to exploration I have been able to remove successfully a teratoma, one containing six pounds of semi-solid sebaceous material.

TREATMENT

Apart from the various forms of *x*-ray therapy, no definite attempts have been made until recently to treat malignant disease of the lung in an adequate way. Owing to its insidious onset, and therefore the comparatively advanced stage which is reached before diagnosis is made, and owing to its position with regard to vital structures, the difficulty of complete removal or adequate irradiation of malignant disease of the lung is obvious. As cases have been classified into two main groups—the parenchymatous and the bronchial—in *x*-ray diagnosis, similarly for treatment they may be grouped as: (1) central growths, (2) bronchial carcinoma.

Central Growths

Unfortunately this group, consisting of growths which offer most chance of surgical extirpation, forms a very small proportion of the total cases of malignant disease of the lung. Of 118 cases of primary malignant neoplasm in the lung which I have personally seen, only nine patients could be put in this category. These nine cases were submitted to exploratory thoracotomy, and six were inoperable because of the presence of secondary malignant glands in the mediastinum or widespread adhesion to the chest wall. The other three, comprising two endotheliomata and one squamous-celled carcinoma, were removed, and are worthy of record.

CASE I.—*Endothelioma of Lung Involving the Right Lower Lobe and Diaphragm*

The patient was a man, aged 60, and the condition necessitated removal of about three-quarters of the right lower lobe and a portion of the diaphragm. The patient died fourteen hours later from haemorrhage from an intercostal artery, which had been penetrated by the needle used in suture of the chest wall.

CASE II.—*Endothelioma of Lower Lobe of Right Lung*

The patient, a woman aged 48, was operated upon in December, 1928. Pain and discomfort were the only symptoms, apart from expectoration of a small quantity of blood-stained mucus on one occasion. The *x* rays showed a definite tumour involving the right lower lobe, and after pneumothorax was induced the lung and its contained tumour were seen to be free from pleural adhesions (Fig. 1). Exploration showed the tumour localized in the lung with no involvement of the mediastinal glands. A small cuff of normal lung was turned back at the hilum, and the lobar artery and vein to the right lower lobe ligatured. The bronchus was crushed and ligatured, and the cuff of pulmonary tissue was sewn over the stump after removal of the lobe. Airtight drainage was employed for forty-eight hours. Apart from a subacute dilatation of the stomach, convalescence was uninterrupted. This patient is alive and without symptoms at the present time, one year and eight months after operation (Fig. 2).

CASE III.—*Squamous-celled Carcinoma of the Lung Involving the Chest Wall*

In July, 1929, the patient, a man aged 55, complained of a slight cough and expectorated a small quantity of blood-stained sputum. *X* rays showed a mass in the left lung, extending to the chest wall. Another skiagram, fourteen days later, showed a similar appearance, but there was now evidence of spontaneous fracture of the sixth rib. There was an area of dullness and dry pleural cracking in the left axilla. Artificial pneumothorax showed adhesion of the mass, which had extended outward from the lung to the chest wall. In September, 1929, exploration was made, and the mass in the lung and the adherent chest wall was removed. This necessitated the excision of the major part of the left lower lobe and portions of three ribs and the intercostal structures between. Airtight drainage was instituted. The general condition was good after operation. The patient improved for a period, but later there was definite evidence of recurrence, from which death ensued about four months later. Histological section of the tumour showed squamous-celled carcinoma.

Of the remaining six cases in this group one patient had multiple primary growths in the right lower lobe with secondary glands in the mediastinum, and eventually died without further treatment. Three others were treated with radon seeds, and will be mentioned later, as will another who was treated by application of a radium plaque externally. One patient with an inoperable growth died from acute bronchitis involving the opposite lung.

Bronchial Carcinoma

This type will rarely offer any hope for successful removal owing to its position and to its early spread into the mediastinal glands. In one case only have I attempted to remove a growth in this region.

CASE IV.—*Carcinoma of Bronchus of Left Upper Lobe*

The patient, a woman aged 27, suffering from haemoptysis, had been treated for some months for pulmonary tuberculosis. *X*-ray examination showed a bilobed shadow in the subapical region of the left upper pulmonary lobe. Its sharp outline suggested a growth, and there was doubt as to whether it was benign or malignant. Pneumothorax, followed by *x* rays, showed the tumour in the lung tissue (Fig. 3). Exploratory thoracotomy on January 8th, 1930, showed the tumour—about the size of a tangerine—to be situated in the upper lobe. The overlying lung was incised, and the tumour was found to lie within an enormously distended bronchus. To this it was attached by a broad base. This base was excised with the tumour, whereon a sudden haemorrhage from the lobar artery ensued. Seizure of the bleeding area was followed by sudden collapse of the patient. A ligature was applied and the lung tissue rapidly sutured over the opened bronchus. Airtight drainage of the chest through a low intercostal stab wound was instituted, and the chest rapidly closed. A small transfusion of 200 c.cm. of blood was followed by rapid improvement of the patient, although the collapse was probably due to vagal shock. Steady convalescence resulted, and the patient is well and symptomless now, eight months after operation (Fig. 4). The growth proved to be a columnar-celled carcinoma.

Radium Treatment

When radical removal is impossible radium therapy should be considered for all growths of a malignant nature in the lung. Three methods are available: (1) teletherapy, application at a distance of large doses (1 to 4 grams) in a bomb; (2) external application of plaques; (3) insertion of radon seeds.

(1) *Teletherapy.*—This method is very attractive, for it does away with any necessity for operation and, being unaccompanied by pain, appeals to doctor and patient alike. My personal experience with this method is limited, and the possibilities of its variations entail a very extended trial before judgement can be passed. However, in those patients—six in number—which have been treated by this method alone, I have yet to see any, even temporary, improvement, and they have all died.

(2) *External Plaques.*—The application of radium on external plaques of Columbia paste or sorbo rubber having proved valuable in other regions, it has been used for five cases of malignant disease of the lung. It is quite obvious that the intensity of the rays in deep growths is so small that no effective action could be expected on growths in the main bronchi, and therefore it should be reserved for growths adjacent to the chest wall. By this method also I have yet to see improvement in the radiological appearance of the neoplasm, although in three cases where the growth had commenced to involve the chest wall and acute pain was a marked feature, the radium application has resulted in considerable amelioration of this symptom.

(3) *Radon Seeds.*—For growths in the main bronchi there are definite dangers of perforation into the mediastinum by haphazard insertion of seeds into the growth itself, and I have therefore devised a small hollow silver tube which carries eight radon seeds. This tube is inserted into the bronchus through the bronchoscope, and a small thread, attached thereto before insertion, passes up through the larynx, and is fixed to the cheek by strapping. The tube has been retained from five to eight days, and appears to cause little irritation. Withdrawal is easily effected by traction on the thread. This method I have used in four patients, but the records are too recent to decide as to its ultimate value. As these growths are often of the squamous-celled variety there is a distinct possibility that we may get a curative result in cases where no extension to the mediastinal glands has occurred before irradiation.

For central neoplasms, and for those arising peripheral to the main bronchi, which are inoperable, the direct insertion of radon seeds would appear to be the method of choice. In every case in which the general condition of the patient does not contraindicate, the growth should be explored, its extent determined, and the seeds inserted as regularly as possible under direct vision. Where adhesions are extensive wide exploration is not possible, and, in these, careful study of skiagrams in various directions will aid in the even distribution of the seeds throughout the growth. Originally the seeds were introduced by one of the types of introducers used for growths elsewhere in the body. In the recent cases I have been employing an ingenious modification, which allows of coagulation of the needle-track by the diathermic current before the trocar is withdrawn. This simple but ingenious modification, which has been suggested by Dickson Wright, prevents the escape from the puncture holes of blood containing tumour cells, and the possible transplantation and development of these cells on the pleural surfaces.

The last three cases which I have treated by this method offer considerable encouragement. In one case the tumour shadow became much less dense and diminished in size, the persistent cough disappeared, and the patient, a man of 68, gained 11 lb. in weight. I have recently heard, eleven months after operation, that he has developed a hemiplegia, which is possibly due to a secondary deposit in the brain. A second patient, a woman of 35, was operated upon in February of last year. When she was examined six months later she had completely lost all sputum; pyrexia and cough were absent, and she had gained well over a stone in weight. *X* rays show almost complete disappearance of the opacity in the lung. The last patient, a man of 64, who also suffered from myocardial changes, is already much improved, although the seeds were only inserted early in June.

Results such as the above are, in my opinion, a distinct encouragement to persevere in the treatment of these cases by radium, and, even if cure cannot be obtained, the relief given and the prolongation of life afforded by these means thoroughly justify the comparatively small risk of the operation.

Deep X-Ray Therapy

This method of treatment has proved very disappointing for primary malignant lung tumours, and I have yet to see a patient who has benefited thereby. The newer and more powerful forms of apparatus may prove of more value, but unless other methods fail I am disinclined to recommend this treatment to my patients at the present time.

Secondary deposits in the lungs are most commonly multiple, and often bilateral. In such cases no question of operative treatment is likely to arise. In rare cases, however, a single secondary deposit may occur in the lung, and in such as the following may justify radical operation.

CASE V.—*Secondary Myeloma in the Left Upper Lobe*

The patient, a woman aged 57, gave the following history. In 1904 she had a myeloma curetted from the upper end of the right fibula. This operation was repeated in 1907. There was another recurrence in 1921, which was treated by radium. This resulted in considerable pain and swelling, and the right lower limb was amputated three weeks later. On July 22nd, 1927, there was a slight attack of haemoptysis. Inquiry elicited a history of a certain feeling of constriction in the upper chest for the previous six months. On examination there was a small patch of dullness over the left apex

posteriorly. X rays showed a well-defined shadow in the apex of the left upper lobe (Fig. 5). Pneumothorax proved the mass to be intrapulmonary, and, in view of the history, probably a secondary deposit (Fig. 6). The upper two-thirds of the left upper lobe were removed through an intercostal incision. Apart from some temporary collapse of the left lower lobe, due to a mucus plug in the bronchus, which was coughed up later, convalescence was uninterrupted (Fig. 7). This patient is alive and symptomless to-day, three years after operation.

Occasionally the rapidity of development of secondary deposits of limited extent in the lungs is diminished by deep x-ray therapy, and this treatment should be recommended only when its limitations are fully realized.

In the past, when a diagnosis of malignant disease was established, the tendency has been to abandon all hope. As diagnosis is becoming possible at an earlier stage it is surely time that some definite efforts should be made to deal with the problem of malignant disease of the lung in a more active way than by palliation of symptoms alone.

CATARACT OPERATION IN EXTREME OLD AGE

BY

R. H. ELLIOT, M.D., F.R.C.S.
LIEUT.-COLONEL I.M.S. (RET.)

It is commonly urged by relations that a patient is "too old for an operation for the removal of cataract." During the course of my experience in cataract operation, running into many thousands of extractions, I have on four occasions operated on patients 90 years old and over, and on one just before her ninetieth birthday. In addition to this I have operated on a very large number of patients between the ages of 80 and 90. No experienced operator will dispute that a cataract extraction is a shock to the patient, and that the lives of some old people are shortened by procedures of the kind injudiciously undertaken. The fact is worth noting that in all five cases the operation was successful, and also the further fact that in not one single instance does it appear to have shortened life. Before discussing the reason for this a few details of these cases may be of interest.

The first patient was a woman in Madras whose skin hung on her in satiny wrinkled folds, resembling the skin of an animal rather than that of a human being. She claimed to be "very, very old," but, like a number of the natives of India, could not give her exact age. She could say, however, that her eldest son fought in one of the Sikh wars. My assistants were able to calculate from this that, even allowing for the very tender age at which Indian women become mothers, she must have been at least 96 at the time of the operation, and possibly several years older. Not only did she make an uninterrupted and perfect recovery, but she signalized the event by stealing a necklace from under a neighbour's pillow the first night that her eye was released from the bandage. The result was that I had to interview her and the outraged lady in the orderly room next morning.

The next case was that of an old retired civil servant, who had long told that an operation for cataract was necessary, refused to have it done until after his ninety-fifth birthday, as he had undertaken to give a bride away on that date. He also made an uninterrupted recovery, and appeared to suffer no shock from the operation. A year later he came to see me, asking me to inspect my golfing eye. He brought with him cuttings from an illustrated paper with his photograph, and the legend beneath it stated that he had made a record "drive" for his age. Considering the very small number of people who play golf at that advanced period, such a statement might readily be accepted. He was asked by a friend at Lucerne his drive, as given in the press, was, he maintained, ten yards short of the length he had really driven. (A true golfer!) I have lost sight of him for a good many years and conclude that he is dead.

The third case was that of an old general who had served many years in the Indian Army. I first operated just after his ninety-fifth birthday for double glaucoma. Six months later I extracted a cataract from one eye. The operations were successful; he stayed only the usual fortnight in the nursing home, and did not appear to be unduly depressed by the shock he had sustained. Whenever I went to see him he had a racy story to tell me. On the occasion of my visit to him in the home on the night before the operation he assured me that he felt quite young, and to satisfy me on this point he insisted on the nurse dancing one of the new steps with him round his room while he vigorously hummed a tune.

In the fourth case the patient was a man very distinguished in public life in his day, and accustomed to having his own way. He had both cataracts extracted towards the close of the ninth decade of his life. An after-cataract formed some time later in one of his eyes. His family were desirous that he should not undergo further operation, and, needless to say, I was very unwilling to undertake any procedure on him after 90 years of age, in view of the fact that the vision was quite reasonably good with the eye in question, while he could read diamond print and had 6/5 vision with the other. I tried to dissuade him, but he turned very determinedly on me and asked, "Do you think I shall see better with that eye if I have it operated on?" I replied, "Yes, but there is an element of risk to your life in this case which I do not feel justified in taking without putting the matter very clearly before you." His reply was, "Well, that is settled. I will come into the home." He was a perfect patient, as he always had been, and once again showed no sign of shock; his recovery was even and uninterrupted, and he regained the sight which he formerly had, equal to that of the other eye.

The fifth patient was operated upon a few months before her ninetieth birthday for a cataract of the Morgagnian variety. The operation was performed in two stages. The patient was stone deaf, and the only possible means of communicating with her was by the hands. We had to establish a code before the operation with signs for "look down," "look up," etc. She was a model patient, and in consideration of her great age she was allowed to sit up in bed the day after the operation. She remained in the home the usual fortnight, making a perfect recovery. Later she was fitted for glasses, though on account of her deafness it was a matter of great difficulty to conduct an accurate test. Her distance vision, under correction, was 6/12, and she read No. 2 (pearl) print easily. She is now over 92, and I recently heard that she was doing well.

Colonel Kirkpatrick has very kindly allowed me to include in this record a case of his own, in an old "John Company" pensioner, 96 years of age, upon whom he operated in Madras. He cannot remember with absolute certainty whether one or both cataracts were extracted, but he is practically sure that the old man came back three or four months later for the second eye to be treated. The point of great interest is that the patient had rhinophyma, causing a marked disfigurement of his nose, and that after the recovery of his sight he insisted on having this operated on at the General Hospital, Madras. He went home with a greatly improved appearance, having regained the strikingly handsome looks of his earlier years—not a bad sequel at about 97.

COMMENTARY

It is probable that very few surgeons have had the opportunity of operating on so many patients at such very advanced ages, and this seems to justify a short note on the cases. What appears to me of much more interest is: (1) that in every one of these cases the operation was successful; and (2) that in none of them was the shock of the operation severe. Remembering how many patients aged 70 or less are in too frail a condition to be submitted

to a cataract operation, and recalling the cases in which it was feared that life was definitely shortened by the shock of the procedure, even though the patient did not die for many months afterwards, the question arises, How is it that these old patients stand operation so well? I think that the answer lies in the extraordinary vitality that has enabled them to live twenty years and longer beyond what is usually accepted as the allotted span of life. The little incidents I have related in connexion with them illustrate the vitality that radiates through these exceptional specimens of the human race. Their protoplasm appears to be of a more active and resistant nature than that of most of their fellows, and I suggest that it this that makes them such good subjects for operation. It is not without significance that such people usually have warm hands and feet—an indication, one may suppose, of an active thermotaxic centre and of excellent circulation. The joy that they obtained out of their restored sight was delightful to see, and I can unhesitatingly say that, given the conditions I have mentioned in these cases, I would sooner operate on such subjects than on many who are only in the sixth and seventh decades of life.

HYDATID DISEASE IN ENGLAND

BY

JAMES F. BRAILSFORD, M.D., M.R.C.S.

THE QUEEN'S HOSPITAL, BIRMINGHAM

(With Special Plate)

Hydatid disease is not a rare disease in this country, although its frequency is much less than in Iceland and in the countries with extensive sheep farming—for example, Australia and the Argentine.

ANIMAL INFESTATION

While investigating the pathological conditions of food animals, I visited the Birmingham public abattoir daily for several years, and every day saw the viscera of sheep, cattle, or pigs infested with the parasite of this disease. Some herds were extensively infested, others free. In a few cases only a solitary cyst was discovered in the animal; in the majority the cysts were multiple, almost completely destroying the normal tissue. The organs so infested were greatly increased in bulk and weight; in some cases cows' livers weighing 200 to 250 lb. were seen, the normal being about 14 lb. (Figs. 1 and 4). Examples of human infestation are seen in hospitals from time to time, and these always attract attention by the variety of the manifestations of the parasitic invasion and by the interesting characteristic features of the hydatid cyst and its contents. No fewer than three hundred articles relative to cases of hydatid disease have been published during the last five years. That we see the disease so frequently in food animals and occasionally in man indicates that conditions are allowed to exist which permit of the completion of the life-cycle of a parasite capable of producing a very dangerous disease in human beings. This is regrettable because, thanks to the researches of Cranwell, Dévé, Dew, Fairley, Graham, Leukart, Thomas, Vegas, and many others, we have the knowledge which would enable us to eradicate the disease from Great Britain as we have done with rabies and other contagious diseases of animals. Every local authority has by-laws which contain a clause prohibiting the dog from slaughterhouse premises, but this by-law is not as strictly enforced as it should be. The parasitic cysts being common in food animals, and not affecting the sale of the meat of the animal, odd cysts are cut off and [illegible] the butcher while trimming the viscera for sale. He thinks no more of the cyst than he would of a clot of blood or other waste fragment. Further, sheep's lungs, which sometimes one has seen so extensively packed with cysts that little normal tissue remains, are not sold for human food; they are put on one side as food for dogs and cats. Dogs are permitted to enter slaughterhouse premises and help themselves to the exposed refuse of the establishment, including any of these odd cysts which may have been thrown on the floor. Again, slaughterhouse refuse is sometimes used for manure, being spread over fields to the joy of all the dogs of the neighbourhood. The adult parasite *Taenia echinococcus* has been found in the wolf, jackal, jaguar, and fox. Obviously only the last may be a source of spread in this country. It is difficult to get foxes for examination, but during the past three years I have examined the intestines of four foxes without finding any echinococci. The part which the fox plays in dissemination could readily be ascertained if a careful inquiry were made into the source of infestation of food animals of the district. At the abattoir are evidences of herds which are badly infested, and if the farms on which these animals are reared were visited, and the dogs known to frequent the particular farms examined, it should easily be possible to find the host or hosts of the adult parasites. Town dogs appear to be fairly free from infestation. In 1920 I made post-mortem examinations on 100 dogs which had been destroyed for various reasons at the Dogs' Home, but in no case did I find *Taenia echinococcus*, although 65 of them were harbouring other tapeworms. I have no doubt from the frequency of the cysts in food animals that the examination of a similar number of dogs in rural districts, particularly sheep dogs, would show a definite number to be harbouring the adult *Taenia echinococcus*. Krabbe discovered the parasite in 25 per cent. of the dogs of Iceland, while 15 to 100 per cent. of the dogs in different districts in Australia have been found to be infested. During recent years the Australian authorities have adopted active measures of prevention, and it is apparent that the percentage of infested dogs has considerably diminished. In this country there is no active propaganda against the parasite. Even the Board of Agriculture and Fisheries does not seem to think it of sufficient importance to issue a leaflet of instruction as it does with diseases of animals much less dangerous and of less economic importance. The possibility of the disease being spread by the cat should not be absolutely ignored, for Dévé has infested the cat experimentally, and cats are frequently fed on raw sheep's lungs. It is probable that the cat is spared infestation by the owner rejecting "lights" containing large cysts, or by the cooking of this food.

HUMAN INFESTATION

Although Dévé has proved experimentally that cysts can develop if the ova are introduced into the bronchi, it is unlikely that many cases of human infestation occur from the inhalation of dust containing ova. Certain possibilities for this exist during the brushing and combing of a dog whose hair has been soiled by faeces containing ova; but a more probable mode of spread is by soiling the hands with ova which are transferred to the mouth, particularly by children whilst eating. It is not always easy to trace the source of infestation. In 1920 I visited the homes of ten patients suffering from, or who had died from, hydatid disease. In one case, where the occupier said that they had never kept a dog, I saw dog excreta on the floor under the table in the living room, and a child crawling about the floor. On pointing this out, I was told that the "mess" had been made by a neighbour's dog, which came in at meal times. I

posteriorly. X rays showed a well-defined shadow in the apex of the left upper lobe (Fig. 5). Pneumothorax proved the mass to be intrapulmonary, and, in view of the history, probably a secondary deposit (Fig. 6). The upper two-thirds of the left upper lobe were removed through an intercostal incision. Apart from some temporary collapse of the left lower lobe, due to a mucus plug in the bronchus, which was coughed up later, convalescence was uninterrupted (Fig. 7). This patient is alive and symptomless to-day, three years after operation.

Occasionally the rapidity of development of secondary deposits of limited extent in the lungs is diminished by deep *x*-ray therapy, and this treatment should be recommended only when its limitations are fully realized.

In the past, when a diagnosis of malignant disease was established, the tendency has been to abandon all hope. As diagnosis is becoming possible at an earlier stage it is surely time that some definite efforts should be made to deal with the problem of malignant disease of the lung in a more active way than by palliation of symptoms alone.

CATARACT OPERATION IN EXTREME OLD AGE

BY

R. H. ELLIOT, M.D., F.R.C.S.

LIEUT.-COLONEL I.M.S. (RET.)

It is commonly urged by relations that a patient is "too old for an operation for the removal of cataract." During the course of my experience in cataract operation, running into many thousands of extractions, I have on four occasions operated on patients 90 years old and over, and on one just before her ninetieth birthday. In addition to this I have operated on a very large number of patients between the ages of 80 and 90. No experienced operator will dispute that a cataract extraction is a shock to the patient, and that the lives of some old people are shortened by procedures of the kind injudiciously undertaken. The fact is worth noting that in all five cases the operation was successful, and also the further fact that in not one single instance does it appear to have shortened life. Before discussing the reason for this a few details of these cases may be of interest.

The first patient was a woman in Madras whose skin hung on her in satiny wrinkled folds, resembling the skin of an animal rather than that of a human being. She claimed to be "very, very old," but, like a number of the natives of India, could not give her exact age. She could say, however, that her eldest son fought in one of the Sikh wars. My assistants were able to calculate from this that, even allowing for the very tender age at which Indian women become mothers, she must have been at least 96 at the time of the operation, and possibly several years older. Not only did she make an uninterrupted and perfect recovery, but she signalized the event by stealing a necklace from under a neighbour's pillow the first night that her eye was released from the bandage. The result was that I had to interview her and the outraged lady in the orderly room next morning.

The next case was that of an old retired civil servant, who, being told that an operation for cataract was necessary, refused to have it done until after his ninetieth birthday, as he had undertaken to give a bride away on that date. He also made an uninterrupted recovery, and appeared to suffer no shock from the operation. A year later he came to see me, asking me to inspect my handiwork, he brought with him cuttings from an illustrated paper with his photograph, and the legend beneath it that he had made a record "drive" for his age. Considering the very small number of people who play golf at 91, the statement might readily be accepted. He was extremely indignant because his drive, as given in the press, was, he maintained, ten yards short of the length he had really driven. (A true golfer!) I have lost sight of him for a good many years and conclude that he is dead.

The third case was that of an old general who had served many years in the Indian Army. I first operated just after his ninety-fifth birthday for double glaucoma. Six months later I extracted a cataract from one eye. The operations were successful; he stayed only the usual fortnight in the nursing home, and did not appear to be unduly depressed by the shock he had sustained. Whenever I went to see him he had a racy story to tell me. On the occasion of my visit to him in the home on the night before the operation he assured me that he felt quite young, and to satisfy me on this point he insisted on the nurse dancing one of the new steps with him round his room while he vigorously hummed a tune.

In the fourth case the patient was a man very distinguished in public life in his day, and accustomed to having his own way. He had both cataracts extracted towards the close of the ninth decade of his life. An after-cataract formed some time later in one of his eyes. His family were desirous that he should not undergo further operation, and, needless to say, I was very unwilling to undertake any procedure on him after 90 years of age, in view of the fact that the vision was quite reasonably good with the eye in question, while he could read diamond print and had 6/5 vision with the other. I tried to dissuade him, but he turned very determinedly on me and asked, "Do you think I shall see better with that eye if I have it operated on?" I replied, "Yes, but there is an element of risk to your life in this case which I do not feel justified in taking without putting the matter very clearly before you." His reply was, "Well, that is settled. I will come into the home." He was a perfect patient, as he always had been, and once again showed no sign of shock; his recovery was even and uninterrupted, and he regained the sight which he formerly had, equal to that of the other eye.

The fifth patient was operated upon a few months before her ninetieth birthday for a cataract of the Morgagnian variety. The operation was performed in two stages. The patient was stone deaf, and the only possible means of communicating with her was by the hands. We had to establish a code before the operation with signs for "look down," "look up," etc. She was a model patient, and in consideration of her great age she was allowed to sit up in bed the day after the operation. She remained in the home the usual fortnight, making a perfect recovery. Later she was fitted for glasses, though on account of her deafness it was a matter of great difficulty to conduct an accurate test. Her distance vision, under correction, was 6/12, and she read No. 2 (pearl) print easily. She is now over 92, and I recently heard that she was doing well.

Colonel Kirkpatrick has very kindly allowed me to include in this record a case of his own, in an old "John Company" pensioner, 96 years of age, upon whom he operated in Madras. He cannot remember with absolute certainty whether one or both cataracts were extracted, but he is practically sure that the old man came back three or four months later for the second eye to be treated. The point of great interest is that the patient had rhinophyma, causing a marked disfigurement of his nose, and that after the recovery of his sight he insisted on having this operated on at the General Hospital, Madras. He went home with a greatly improved appearance, having regained the strikingly handsome looks of his earlier years—not a bad sequel at about 97.

COMMENTARY

It is probable that very few surgeons have had the opportunity of operating on so many patients at such very advanced ages, and this seems to justify a short note on the cases. What appears to me of much more interest is: (1) that in every one of these cases the operation was successful; and (2) that in none of them was the shock of the operation severe. Remembering how many patients aged 70 or less are in too frail a condition to be submitted

to a cataract operation, and recalling the cases in which it was feared that life was definitely shortened by the shock of the procedure, even though the patient did not die for many months afterwards, the question arises, How is it that these old patients stand operation so well? I think that the answer lies in the extraordinary vitality that has enabled them to live twenty years and longer beyond what is usually accepted as the allotted span of life. The little incidents I have related in connexion with them illustrate the vitality that radiates through these exceptional specimens of the human race. Their protoplasm appears to be of a more active and resistant nature than that of most of their fellows, and I suggest that it this that makes them such good subjects for operation. It is not without significance that such people usually have warm hands and feet—an indication, one may suppose, of an active thermotaxic centre and of excellent circulation. The joy that they obtained out of their restored sight was delightful to see, and I can unhesitatingly say that, given the conditions I have mentioned in these cases, I would sooner operate on such subjects than on many who are only in the sixth and seventh decades of life.

HYDATID DISEASE IN ENGLAND

BY

JAMES F. BRAILSFORD, M.D., M.R.C.S.

THE QUEEN'S HOSPITAL, BIRMINGHAM

(With Special Plate)

Hydatid disease is not a rare disease in this country, although its frequency is much less than in Iceland and in the countries with extensive sheep farming—for example, Australia and the Argentine.

ANIMAL INFESTATION

While investigating the pathological conditions of food animals, I visited the Birmingham public abattoir daily for several years, and every day saw the viscera of sheep, cattle, or pigs infested with the parasite of this disease. Some herds were extensively infested, others free. In a few cases only a solitary cyst was discovered in the animal; in the majority the cysts were multiple, almost completely destroying the normal tissue. The organs so infested were greatly increased in bulk and weight; in some cases cows' livers weighing 200 to 250 lb. were seen, the normal being about 14 lb. (Figs. 1 and 4). Examples of human infestation are seen in hospitals from time to time, and these always attract attention by the variety of the manifestations of the parasitic invasion and by the interesting characteristic features of the hydatid cyst and its contents. No fewer than three hundred articles relative to cases of hydatid disease have been published during the last five years. That we see the disease so frequently in food animals and occasionally in man indicates that conditions are allowed to exist which permit of the completion of the life-cycle of a parasite capable of producing a very dangerous disease in human beings. This is regrettable because, thanks to the researches of Cranwell, Dévé, Dew, Fairley, Graham, Leukart, Thomas, Vegas, and many others, we have the knowledge which would enable us to eradicate the disease from Great Britain as we have done with rabies and other contagious diseases of animals. Every local authority has by-laws which contain a clause prohibiting the dog from slaughterhouse premises, but this by-law is not as strictly enforced as it should be. The parasitic cysts being common in food animals, and not affecting the sale of the meat of the animal, odd cysts are cut off [illegible] by the butcher while trimming the viscera for sale. He thinks no more of the cyst than he would of a clot of blood or other waste fragment. Further, sheep's lungs, which sometimes one has seen so extensively packed with cysts that little normal tissue remains, are not sold for human food; they are put on one side as food for dogs and cats. Dogs are permitted to enter slaughterhouse premises and help themselves to the exposed refuse of the establishment, including any of these odd cysts which may have been thrown on the floor. Again, slaughterhouse refuse is sometimes used for manure, being spread over fields to the joy of all the dogs of the neighbourhood. The adult parasite *Taenia echinococcus* has been found in the wolf, jackal, jaguar, and fox. Obviously only the last may be a source of spread in this country. It is difficult to get foxes for examination, but during the past three years I have examined the intestines of four foxes without finding any echinococci. The part which the fox plays in dissemination could readily be ascertained if a careful inquiry were made into the source of infestation of food animals of the district. At the abattoir are evidences of herds which are badly infested, and if the farms on which these animals are reared were visited, and the dogs known to frequent the particular farms examined, it should easily be possible to find the host or hosts of the adult parasites. Town dogs appear to be fairly free from infestation. In 1920 I made post-mortem examinations on 100 dogs which had been destroyed for various reasons at the Dogs' Home, but in no case did I find *Taenia echinococcus*, although 65 of them were harbouring other tapeworms. I have no doubt from the frequency of the cysts in food animals that the examination of a similar number of dogs in rural districts, particularly sheep dogs, would show a definite number to be harbouring the adult *Taenia echinococcus*. Krabbe discovered the parasite in 25 per cent. of the dogs of Iceland, while 15 to 100 per cent. of the dogs in different districts in Australia have been found to be infested. During recent years the Australian authorities have adopted active measures of prevention, and it is apparent that the percentage of infested dogs has considerably diminished. In this country there is no active propaganda against the parasite. Even the Board of Agriculture and Fisheries does not seem to think it of sufficient importance to issue a leaflet of instruction as it does with diseases of animals much less dangerous and of less economic importance. The possibility of the disease being spread by the cat should not be absolutely ignored, for Dévé has infested the cat experimentally, and cats are frequently fed on raw sheep's lungs. It is probable that the cat is spared infestation by the owner rejecting "lights" containing large cysts, or by the cooking of this food.

HUMAN INFESTATION

Although Dévé has proved experimentally that cysts can develop if the ova are introduced into the bronchi, it is unlikely that many cases of human infestation occur from the inhalation of dust containing ova. Certain possibilities for this exist during the brushing and combing of a dog whose hair has been soiled by faeces containing ova; but a more probable mode of spread is by soiling the hands with ova which are transferred to the mouth, particularly by children whilst eating. It is not always easy to trace the source of infestation. In 1920 I visited the homes of ten patients suffering from, or who had died from, hydatid disease. In one case, where the occupier said that they had never kept a dog, I saw dog excreta on the floor under the table in the living room, and a child crawling about the floor. On pointing this out, I was told that the "mess" had been made by a neighbour's dog, which came in at meal times. I

7 years old, but I was unable to find any echinococci in its intestines. Owing to the fact that infestation may take place as long as ten years before the hydatid cyst is detected, it is extremely difficult for the patient to say when or how it may have occurred. This is very different with food animals, as they may be killed within six to twelve months of being infested, and in consequence the host of the adult be more readily detected. Ordinary house flies may deposit on food the ova from their legs. The contamination of lettuce and other salad material by dogs is also a possibility which must not be neglected. Infection of the water supply has been seriously suggested by various Australian workers, but although in certain cases it may occur, as a rule in this country it would be a most unlikely source of infestation.

CHARACTERISTICS OF TAENIA ECHINOCOCCUS

The adult *Taenia echinococcus* is only about 1/8 inch long, and consists of a head and neck with three segments —the last segment being about one-half of the entire length of the worm, and containing about one thousand ova. The head has four suckers and a rostellum of about thirty-six hooklets. Several forms of the genus *Echinococcus* are referred to by Cameron. Infested dogs usually harbour a very large number of adult worms ; so numerous and so close together are they that some authorities have likened the appearance of the worms on the inside of the intestine to the pile on plush. The innumerable scolices which exist in one cyst account for this (Fig. 2). It will be obvious, therefore, that the faeces of an infested dog may possess an enormous number of ova. These ova, having been swallowed, are attacked by the gastric juice, which dissolves the outer shells and sets free embryos having six spines. These embryos obtain access to radicles of the portal vein and are carried to the liver. In the liver most of the embryos settle and develop into hydatid cysts, but a proportion get through into the general circulation via the inferior vena cava and the right heart, from which they are carried to any tissue of the body, where they ultimately come to rest and develop into hydatid cysts. There does not appear to be any selective affinity of the parasite for any particular organ, as is the case with the embryos of some of the other Taenia. Thus, the embryos of *Taenia serialis* appear to have an affinity for the connective tissues, the embryos of *Taenia cenurus* for the brain, and the embryos of *Taenia serrata* and *Taenia marginata* for the subserous tissues, while the embryos of *Taenia solium* seem to have an affinity for muscle and nerve tissue. This is well illustrated by the photograph (Fig. 3), which shows subserous cysts of *Cysticercus pisiformis* beneath the peritoneum of the organs of a rabbit. These embryos presumably pass through the liver, but develop only in special tissues or sites. That the reason for the greater frequency of the cysts in the liver may be a mere filtration of the parasite from the blood is not likely, because the majority of hydatid cysts in the liver are subserous, although deep cysts do occur (Fig. 4).

HYDATID CYSTS IN MAN

The average frequencies of hydatid cysts in man appear to be about 70 per cent. liver, 10 per cent. lungs, 2.5 per cent. kidneys, 2.5 per cent. spleen, 5 per cent. other abdominal organs, 5 per cent. muscles and cellular tissues, 5 per cent. brain, and 1 per cent. bones. Some authorities find a higher percentage of pulmonary cysts in children. A number of pulmonary cysts rupture into a bronchus and cure takes place, estimated by some workers as occurring in 50 per cent. of cases. In 25 per cent. of the cases which occur in man multiple cysts are found. The rate of development in size of the cyst appears to vary with different tissues. In the lung it reaches about 1/2 inch in diameter in six months. Edwards has recorded the development of a cyst 2 inches in diameter in one year. The cyst may grow to a great size. Dévé has reported a cyst of the abdomen which held 22 pints of fluid. The adventitious sheath of the cyst may in time become calcified. Usually the cysts in the lungs are single, and possess a laminated cyst wall, on the inner side of which are seen brood capsules of the size of sand particles and white in colour (Fig. 2). Older cysts frequently contain daughter cysts. It is now generally believed that the formation of daughter cysts is related to trauma of the parent cyst, for where the parent cyst is protected, as in the bony thorax or the skull, it is frequently single. On the other hand, in those cases where rupture, either natural or through surgical treatment, has occurred, daughter cysts are invariably found. Dew says that this theory is supported by the fact that practically all cysts containing daughter cysts give a positive complement-fixation test, whereas a good proportion of simple cysts may fail to give a positive test. These daughter cysts may be set free by rupture of the parent cyst and become attached to other structures, or they may lie free in the abdominal cavity and develop into large secondary cysts. The condition called by Dévé secondary echinococcosis may be produced by the rupture of the parent cyst and the development of multiple cysts from the scattered brood capsules, scolices, or cells of the germinal layers of the cyst. In some cases an intense reaction is set up by the serous membranes, soiled by the spilt cyst contents, and the parasitic elements are destroyed. Rupture of a hydatid cyst into the heart is usually associated with multiple cysts of the brain. Hydatid cysts have been found in most structures of the body. Though, as we have seen, the majority of cysts occur in the liver, in some cases this organ is missed, and an isolated cyst is found in some other tissue. If, however, a cyst has been found in any other part, the possibility of one or more liver cysts should not be overlooked. The fluid is under great pressure, and consequently may push aside adjoining structures, but the process is so slow that pain is rare until the cyst has attained a large size, has ruptured, or has become infected with bacteria. It may therefore remain symptomless for years, and may then be detected only accidentally during an *x*-ray examination or owing to rupture from trauma.

CLINICAL FEATURES

An investigation which leads to the detection of the cyst may be undertaken because of the pressure effect of the cyst on the structures containing or adjoining it. Hydatid cysts have supplied the clinician with every physical sign, and called for investigation with almost every laboratory test. In the thorax the cyst may displace the heart, big vessels, trachea, bronchi, or oesophagus. It may produce erosion of the vertebrae or ribs adjoining the cyst. It may rupture into the heart, pericardium, bronchus, oesophagus, vena cava, or pleura. In the liver the cyst may push up the diaphragm, compress or rupture into the biliary ducts, portal vein, duodenum, pleura, bronchus, or peritoneal cavity. Similarly, cysts in other abdominal organs may displace neighbouring large vessels and organs. In the brain are produced symptoms of increased intracranial pressure, displacement of or rupture into the ventricle, and erosion of the skull, the cyst becoming superficial. In the spine symptoms of spinal tumour may occur, and the cyst may erode the vertebrae and rupture into the spinal canal. In the musculature the cyst may be ruptured and the contents disseminated throughout the area, with later development of secondary cysts. In bone the cyst has a greater resistance to overcome, and its progress appears to be slower, but in time the structure of the bone is destroyed

and replaced with a large cystic tumour, having a shell of thin bone. The strength of the bone is obviously considerably weakened, and ultimately fracture results.

RUPTURE OF CYST

Following the rupture of the cyst in any of these sites, the cyst and its contents may become septic, and symptoms of septic poisoning or localized inflammation may develop. The rupture of a cyst may be accompanied by rupture of blood vessels in the vicinity; particularly is this seen in the case of lung cysts. Some authorities state that haemoptysis occurs in 60 per cent. of patients with pulmonary hydatid cysts. The bronchi or trachea may be blocked by large pieces of hydatid membrane or by daughter cysts. Urticaria, pruritus, erythema, sweating, asthmatic cough, cyanosis, dyspnoea, oedema, nausea, vomiting, diarrhoea, tenesmus, syncope, collapse, delirium, coma, pallor, and tachycardia are some of the more urgent symptoms which may develop from the rupture of a hydatid cyst. Death has occurred from rupture due to anaphylactic shock, asphyxia, pulmonary oedema, and embolism. I can imagine nothing more horrifying happening to a man or woman who looks and feels very fit than the sudden rupture of a pulmonary cyst. The sudden pain and expulsion of hydatid fluid, membranes, and perhaps, later, blood down the nostrils and through the mouth, the suffocation, the marked dyspnoea, the profound shock, and a feeling of impending death, are among the features of such an event. Pictures of such recollections are described by two students, Chachereau and Marconnet.

DIAGNOSIS

The finding of hydatid membrane, scolices, or hooklets in sputum, vomit, urine, excreta, or discharge from a sinus is the most conclusive evidence of the presence of the disease. The temptation to obtain this evidence by puncture of a doubtful cyst is fraught with grave danger, and may result in the sudden death of the patient. The fluid in a hydatid cyst is under great pressure, and when the membrane is punctured the sudden release of tension may cause a large tear of the membrane similar to that found in the bursting of toy rubber air balloons. Particularly in such tissues as the lungs is this likely to happen, when not only the cyst wall, but the layer of lung tissue, including the blood vessels surrounding any adjoining bronchus, are torn, and hydatid fluid and membrane are forcibly propelled into the bronchial tree. Numerous instances of sudden death from this cause have been recorded. Bristow speaks of the death of an otherwise apparently healthy boy, 9 years of age, which occurred within six minutes of pushing an aspirating needle into a hydatid cyst of the left lung. At post-mortem it was found that the cyst had ruptured into a bronchus. Puncture of a hydatid cyst of the brain usually results in immediate rupture of the cyst into the ventricle.

The percentage of eosinophils in the blood may be of value in suggesting the possibility of hydatid disease. Unfortunately, these cells are increased in most helminth infestations, in some skin diseases, and after the taking of certain drugs. Fairley regards 300 eosinophil cells per cubic millimetre as the upper normal limit, and states that with hydatid disease as many as 500 per cubic millimetre may be found.

A positive precipitation test is indicated by a fine flocculent precipitate forming in the course of thirty-six hours in prepared hydatid fluid on the addition of the serum of a patient affected with hydatid disease. Dew says that this precipitation is obtained in about 65 per cent. of hydatid patients. The test is only of value when measured against the results obtained with carefully prepared controls.

The intradermal test for hydatids introduced by Casoni is of great value, and gives a high percentage of positive results in the presence of simple cysts. It was suggested by the skin eruptions which are frequently produced by the rupture of a hydatid cyst and the absorption of hydatid fluid into the blood. The test has been elaborated by Bull and others, and is performed by the intradermal injection of prepared sterile hydatid fluid. An immediate reaction with a delayed phase in some cases indicates a positive result. Particulars of the test are given by Dew, who states that in uncomplicated cysts an immediate reaction and delayed phase are obtained in 90 to 95 per cent. of cases, whereas with the presence of ruptured cysts the delayed phase may be absent. Dew further states that the test is of extreme importance, in that a reaction can be detected in many cases in which no complement fixation is obtained. Thus, in simple cysts of the lungs and liver in children, positive results are universally obtained.

Bordet and Gengou have shown that the same complement will unite with both haemolytic and bacteriolytic immune bodies. This phenomenon of Bordet and Gengou has been used for the detection of immune bodies in the blood serum of patients suffering from hydatid disease. Most of the patients who have cysts which have ruptured naturally, or have received surgical intervention, give a positive complement-fixation test, but the test may be negative if an unruptured or dead cyst be present. Consequently the test may be misleading, particularly in children, in whom the cysts are mostly simple.

As the hydatid cyst may exist for years without producing any specific symptoms, the first suggestion of this disease may be obtained during an *x*-ray examination. The patient may have had a haemoptysis and is radiographed because of the suspicion of tuberculosis. On the screen, or better still on a radiogram, an abnormal shadow will be seen. The features of the hydatid cyst of the lung, as shown on a radiogram, depend on the condition of the cyst. If it is a simple cyst and unruptured, it will appear usually as an ovoid shadow, uniform in density, with a well-defined margin, and without any changes in the lung tissue around (Figs. 5 and 6). If it has ruptured, only the outline of the cyst may be shown, and it may be mistaken for a pleural ring (Fig. 5). The introduction of lipiodol into the involved bronchus may give a better idea of the nature of the shadow. The cyst contents may have been only partially evacuated, and a fluid line may be shown, or more fluid may collect in the evacuated cyst in the course of a day or so and show as encysted fluid on *x*-ray examination. Calcified cyst walls cast a dense shadow, and their appearance is very suggestive. Cysts near the mediastinum or ribs produce radiographic appearances which are simulated by a number of other pathological conditions, such as fibroma, primary sarcoma, dermoid cysts, interlobar collection of fluid, secondary sarcomata, carcinomata, and other neoplasms, pyaemic abscesses, or aneurysm. Some of these are shown in Figures 7 and 8, and good illustrations are given by Belot and Peutenil in their monograph. In suggesting the diagnosis of a hydatid cyst of the lung I now attach more importance to the continuity and regularity of outline, and the ovoid rather than the spherical shape, although even these may be seen with secondary neoplasms (Figs. 7 and 8).

The *x*-ray shadows of fibroma and secondary neoplasms tend to be more spherical, but I have seen secondary tumours which, owing to central degeneration, liquefaction, and, later, rupture into a bronchus, have shown a fluid level, and given the radiographic appearance of a hydatid cyst half full of fluid (Fig. 9). It is therefore important to correlate the *x*-ray findings with the results of the laboratory tests already enumerated, and with the

clinical findings, before finally coming to a definite decision. If the cyst in the lung has ruptured, and the neighbouring tissue has been infected, it may be impossible to distinguish the condition from other inflammatory lesions. In some cases where this has occurred the radiographic appearances may give no suspicion of hydatid cyst. Cysts in the abdomen may not show any shadow on the radiogram unless there has been a deposition of lime salts in its wall or contents. If this has taken place, the outline of the cyst may be distinctly shown, and where cysts have been discovered in the lungs it is advisable to try to get this additional evidence. Some workers have shown hydatid cysts in the liver and spleen by radiograms after pneumoperitoneum has been performed. Radiograms of the skull in suspicious cases of hydatid disease with cerebral symptoms may show erosion of the bone and displacement of the shadow of the pineal gland. Owing to the grave danger of rupture of hydatid cysts of the brain into the ventricle, it is most unwise to perform ventrilography where this condition is suspected. Hydatid disease of the bone simulates giant-celled myeloma in its radiographic appearance. The characteristic radiographic features are well illustrated in the articles by Bauer and Gold. The latter has a radiogram showing cystic destruction of one side of the pelvis and upper third of the femur.

CONCLUSIONS

1. Hydatid disease is not rare in this country.
2. It has a high mortality rate.
3. It could be eradicated by the burning of all hydatid cysts and the isolation of infested dogs until all adult parasites had been expelled and destroyed. This could be accomplished by (*a*) education of the public, particularly butchers and farmers, by suitably illustrated leaflets and posters for slaughterhouse premises. (*b*) Strict enforcement of the by-laws prohibiting dogs in slaughterhouse premises. (*c*) Compulsory notification of all cases of hydatid cysts and the destruction of the cysts by the sanitary authorities. (*d*) The inspection of farms on which the infested animals were reared, and isolation treatment of all suspicious dogs.

I wish to express my thanks to Dr. G. B. Dixon and Mr. W. Smith of the tuberculosis department for permission to include the radiograms 5 and 6.

THE MEINICKE CLARIFICATION REACTION

BY

DAVID PRENTICE, M.B., CH.B.GLAS.

ASSISTANT MEDICAL OFFICER, COUNTY MENTAL HOSPITAL, WHITTINGHAM, LANCASHIRE

The second laboratory conference on the serodiagnosis of syphilis was held in Copenhagen, under the auspices of the Health Organization Section of the League of Nations, from May 21st to June 4th, 1928. An examination was made of 944 specimens of serum from various cases by means of seven modifications of the Bordet-Wassermann test, and also by various flocculation procedures, including the tests of Kahn, Meinicke (turbidity), Muller (clotting), Murata, Sachs-Georgi, and the modified sigma, and the Vernes syphilimetric tests.

One of the conclusions reached at the first conference, which was held in 1923, was that "flocculation tests cannot replace the Bordet-Wassermann test." Since then the flocculation tests have been improved in technique, and now the recent conference "is of opinion that the best of them may be regarded as equal in value to the best of those which depend on fixation of complement (Bordet-Wassermann)." It also "recommends that, in order to secure the most reliable information to the clinician, at least two different serodiagnostic methods should be used." A majority of the eminent serologists who performed the tests would prefer for the present that one of the methods should be a Bordet-Wassermann test.

The conference stated that the Kahn and Muller tests were superior in sensitiveness to all other methods. The Kahn reaction is difficult to read, and involves the measuring of small quantities of serum by means of capillary pipettes. The performance of the Muller test is rather difficult, and in both procedures the serum has to be inactivated.

In consequence of this report Meinicke has modified his turbidity reaction (M.T.R.), and has produced the Meinicke clarification reaction (M.K.R.), in an endeavour to increase the sensitivity of his test. Since June, 1926, the Meinicke micro-reaction, a modification of the M.T.R., has been performed in all cases at the Whittingham Mental Hospital, and our preliminary results have been published.[1,2] Meinicke has now prepared a modification of the M.K.R., enabling it to be used as a micro-test, and reported this method in a letter dated April 11th, 1929, to the medical superintendent of this hospital, Dr. Clark.

We have tested both the M.K.R. and its micro-modification on a number of patients, and can now give an opinion on its sensitivity, reliability, and ease of performance.

THE MEINICKE MACROSCOPIC REACTION

Principle

An ether extract of ox heart is diluted with alcohol, and balsam of tolu is added. When this is mixed with a 3.5 per cent. solution of sodium chloride containing various quantities of sodium carbonate, extract dilutions are formed which are densely milky, turbid, and opaque. To this extract dilution active serums are added. With a positive serum a clarifying of the fluid takes place within twenty hours (clarification reaction). In a negative case there is no clarification; the fluid remains turbid.

Technique

Serum.—This is centrifuged and then placed in a test tube; it must not be heated or inactivated. Haemolytic, icteric, and cloudy serums are all adaptable to the reaction.

Antigen.—This may be obtained from Dr. Meinicke's laboratory (Elberfelder Strasse, 74, Hagen, Westphalen, Germany). It should be kept at room temperature and be protected from light; the bottle should have a cork stopper.

Salt Solution.—Two stock solutions are used—namely, (*a*) a 3.5 per cent. solution of sodium chloride, and (*b*) a 1 per cent. solution of sodium carbonate in 3.5 per cent. salt solution. Four dilutions of the soda solution are required for the test:

0.01 per cent. made by adding 1 part of (*b*) to 99 parts of (*a*).
0.015 per cent. made by adding 1.5 parts of (*b*) to 98.5 parts of (*a*).
0.02 per cent. made by adding 2 parts of (*b*) to 98 parts of (*a*).
0.04 per cent. made by adding 4 parts of (*b*) to 96 parts of (*a*).

Method

Antigen-soda dilution mixture.—Four test tubes, each containing 10 c.cm. of the various soda dilutions, and another four each containing 1 c.cm. of antigen, are placed in a water bath and left there for ten minutes at 45° C. Each tube of soda-salt solution is then rapidly mixed by pouring backwards and forwards with 1 c.cm. of the antigen. The resulting antigen mixture is milky and entirely opaque. It should be allowed to mature for two minutes. Four test tubes, A, B, C, and D, each 8 cm. in length and 1 cm. in diameter, are set up in rows in a rack; 0.2 c.cm. of the serum is pipetted into tubes A, B, and C, while 0.1 c.cm. of the serum is pipetted into tube D, and to this is added 0.1 c.cm. of the 0.04 soda solution.

To A is added 0.5 c.cm. of 0.01 per cent. extract dilution.
To B is added 0.5 c.cm. of 0.015 per cent. extract dilution.
To C is added 0.5 c.cm. of 0.02 per cent. extract dilution.
To D is added 0.5 c.cm. of 0.04 per cent. extract dilution.

The time taken in pipetting the antigen mixture into the tubes with serums should not be more than ten minutes. Eight different serums can generally be tested in this time. The racks are then well shaken, and are left for twenty hours in a room at a temperature of about 20° C.

Reading of the Results

In a negative reaction the fluid in the test tubes is milky and opaque as before. In a strongly positive reaction a complete clarification has taken place in the test tubes, so that the cross-bar of a window two or three yards away is distinctly visible. In a weaker positive the fluid is more or less opalescent, but the cross-bar can be seen through it.

In most of the tubes a certain amount of sedimentation takes place, but it is the opacity and not the sedimentation which is the guide to the reading of the result. Should only the last tube (D) be clear, and the other three slightly opaque, the reaction must still be considered strongly positive.

Sixty-five specimens were examined and a confirmatory Wassermann test was performed on each at the University of Manchester. There was agreement between the two tests in 92.4 per cent. of these cases. In two of the five cases which disagreed the result of the M.K.R. was *doubtful*.

In reading the results tubes A, B, and C were found to give unreliable results. In twenty-one cases out of the sixty-five the reading in one or more of them differed from that of tube D. *Our results are all based on the reading of tube D*, which we consider the only one really necessary for the reliable performance of the test. By using it alone the test could be much simplified.

THE MICROSCOPIC MODIFICATION

The principle of the test is the same as for the M.K.R.

Serum.—The blood collected from a finger-prick is passed along a capillary tube 10 cm. in length by 1 mm. inside diameter. Two-thirds of the tube are filled, and the empty end is sealed by a flame, care being taken that the blood is not heated. Only when the capillary has *to be sent* away need the other end be sealed with wax. The tube is now left for a few hours in a cool place in a horizontal position and then centrifugalized towards the sealed end. The clear serum collects in the centre and is ready for use when the tube has been filed and broken, and the contents tapped or blown on to a clean numbered slide.

Antigen.—The same extract is used as for the M.K.R. The soda-salt dilution required is made by adding 3 c.cm. of a 1 per cent. solution of sodium carbonate in 3.5 per cent. salt solution to 97 c.cm. of a 3.5 salt solution—that is, by adding 3 parts of stock solution (*a*) to 97 parts of stock solution (*b*). This gives a 0.03 per cent. soda-salt dilution. Then 1 c.cm. of the extract and 10 c.cm. of the soda-salt dilution are placed in test tubes and incubated in a water bath at 45° C. for ten minutes. They are then mixed by pouring rapidly several times from one to the other. The resulting extract dilution is then poured into a warmed porcelain crucible, and covered with a watch glass; there it must "ripen" for two minutes before the test is performed. It is milky and entirely opaque, and should not be kept longer than ten to fifteen minutes, in which time fifteen serums can be mixed with it.

Mixing.—Two platinum eyelets are used for the admixture. The larger, 4 mm. in diameter, is attached horizontally to a small porcelain stand, and a loopful of the extract dilution is taken on it. On the smaller, which is 2 mm. in diameter, serum is taken. They are mixed by passing the smaller eyelet several times rapidly through the lumen of the larger. A drop of the mixture from the smaller is now placed on a clean coverslip, and a hanging drop preparation is made; this is allowed to stand for one hour in a moist atmosphere at room temperature. As each fresh serum is examined the platinum eyelets are dipped in water and next in alcohol; they are then flamed. They must be cool before being used again, and it is better, therefore, to have two pairs of eyelets.

Examination.—After an hour the slides can be read, a microscope with weak ocular and dry objective magnifying about sixty times being used. A negative reaction shows an even, finely granular field in which the particles are lively. In a positive reaction agglutination occurs, and large, widely separated dark-brown clumps are seen. Where the reaction is weakly positive the clumps are smaller and closer together. On one occasion a delayed positive reaction was noted. It is advisable, therefore, to re-examine the slides eight or nine hours after the test has been completed.

RESULTS

Since April, 1929, 384 serums have been examined, and a confirmatory Wassermann test has been performed on ninety-five of these cases. Our routine is that a nurse collects the serum from the new admissions and from other cases as directed by the medical officer, and they are then sent to the laboratory in lots of about ten at a time, and examined. Where the Meinicke reaction is positive, and in all suspicious cases, a specimen is always sent away for a Wassermann test.

There was agreement between the two tests in 92.7 per cent. of the cases. In the seven which differed the Meinicke was positive *in six cases and doubtful in the* other, while the Wassermann reaction was negative in all.

We are of the opinion that a reliable microscopical test has many advantages to offer over any of the macroscopical methods in which a large quantity of serum is required. Especially is this the case when dealing with children, resistive and troublesome patients, the obese, and those in whom the veins are poorly developed.

CONCLUSIONS

The Meinicke clarification reaction can be simplified by eliminating three of the tubes containing serum (A, B, and C) and using only tube D. Its micro-modification is rapid in operation, gives a high percentage of agreement with the Wassermann reaction, is very sensitive, and is easy both to perform and to read. As a routine test for syphilis in the patients admitted to a mental hospital it offers advantages over any other test. It has proved both serviceable and reliable.

My thanks are due to Dr. R. M. Clark, medical superintendent, under whose general supervision this work has taken *place, for permission* to publish these results, and also to Mr. A. H. Fann, senior laboratory assistant, for help with the technical *part of the work.*

FURTHER OBSERVATIONS ON OVARIAN TRANSPLANTATION.

BY

JOHN H. HANNAN, M.D.*

REGISTRAR AND PATHOLOGIST TO THE HOSPITAL FOR WOMEN, SOHO

My work on this subject during 1929[1 2] indicated the results obtained by (1) transplantation of ovaries, removed from rabbits, into other rabbits (twenty transplantations); (2) transplantation of ovaries, removed from cats, into rabbits (twenty transplantations).

The site chosen in this series was a pocket, framed between the superficial and deep fasciae of the back of the receiving animal. Sections were taken of transplanted ovaries removed at regular intervals, and examination of these revealed no trace of ovarian tissue in transplants older than six weeks. Further, the occurrence of heat, acceptance of the male, and the other signs associated with full ovarian activity steadily declined as the graft degenerated, until complete sexual senility was observed at the time when no ovarian tissue could be found in the transplants.

In 1930 human ovaries were transplanted into monkeys (*Macacus rhesus*)—five transplantations in all. These were performed in two situations—namely, (1) between the layers of the broad ligament, and (2) subcutaneously.

* Working under a grant from the British Medical Association.

Results with this technique were no better than those reported previously. In short, my attempts to transplant ovaries which would continue their physiological function have proved entirely unsuccessful.

So many claims in this field of research have been made of recent years that the time has come to consider the whole question in the light of the available evidence. Microscopical evidence of the survival of the transplanted glands can be the only evidence accepted, and a study of the literature shows that such evidence is in inverse proportion to the number of papers published.

That the stroma cells of the ovary may persist for some time in transplants I do not deny; but as to the value of these modified connective tissue cells in the preservation of the endocrine function of the ovary, I can only refer to modern researches in ovarian physiology. Research in this field has proved conclusively that the physiological function of the ovary depends upon an active Graafian follicular system—that is, the maturation of the follicles and the formation of the corpus luteum. On the evidence, I maintain that this follicular mechanism continues to function for only a few weeks in transplanted ovaries.

Is there any clear evidence that a compound gland can be transplanted in such a manner that its full physiological function can be maintained? We know that the physiological activity of a compound gland depends upon three factors: (1) the blood supply and drainage, (2) the lymphatic supply and drainage, (3) the nerve supply. Allowing that surgical technique may develop to such an extent that the blood supply and drainage can be assured by the anastomosis of the vessels of the transplanted gland to the vessels of the bed in which the transplant rests, can we offer any hope of being able to deal effectively with the lymphatic supply and drainage? I do not think so. With regard to the nerve supply, even if it were possible to anastomose the nerve supply of the transplant to the nerve supply of the bed, regeneration of the anastomosed nerves would take place only a considerable time after trophic changes had occurred in the transplant. On the available evidence, therefore, I consider that the transplantation of a compound gland, such as the ovary, is of no value, since its physiological activity cannot be maintained.

Moreover, a consideration of the anatomy and physiology of a compound gland such as the ovary, and of modern surgical research on compound glands in general, affords no prospect of successful ovarian transplantation in the future.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

AN EPIDEMIC OF DYSENTERY DUE TO B. DYSENTERIAE γ OF HISS

In view of the increasing interest in bacillary dysentery, and the accumulating evidence of a hitherto unsuspected incidence of the disease in this country, it would be of interest to put on record what appears to have been another outbreak, although as a private practitioner I am able to give bacteriological evidence in regard to two cases only.

During July, 1929, a large number of cases of diarrhoea came to my notice. The severity of the infection varied, but the great majority were of a mild character, the symptoms being frequent loose, watery motions, up to a dozen a day, with colicky pains in the abdomen, and tenesmus at the time of movement, sufficient to give rise to considerable discomfort and general malaise, leaving a feeling of weakness afterwards. Those mild cases had no rise of temperature, and there was only occasionally a little blood in the stools. In older and not so robust people the general disturbance was more marked at the time of the diarrhoea, there being a slight rise of temperature to 99°, 99.5°, or 100°; the prostration remaining was more appreciable. In a few exceptional cases the illness was definitely febrile, the highest temperature noted being 104°.

Although I was not so keenly aware then as I am now of the incidence of bacillary dysentery in this country, it soon became evident after the first few cases that this was an infectious disease; I concluded that it was probably of the nature of a summer diarrhoea, and I thought it might be fly-borne. The weather at the time was warm.

The mildly infected patients were not sufficiently incapacitated to have to remain off work. With a course of a saline cathartic, and restriction of diet to bovril and similar fluids, practically all were feeling well in forty-eight hours, but the older people felt a more lasting weakness. Even the more severe cases with fever were convalescent within four days. Besides those actually treated, I heard of a good many more people affected by diarrhoea at the same time who did not seek medical advice.

The disease was widespread, and not confined to any locality or to any class, though it was not quite so prevalent among the leisured class as among the working and business classes. No case was of sufficient severity to warrant the expense of further investigation till there occurred the sudden death of a boy, aged 7, which was the means of throwing light on the epidemic.

At 1.10 a.m. on July 28th, I was asked to go and see two brothers, J. W., aged 7, and M. W., aged 6, who were said to be vomiting and to be delirious. The history of the beginning of the trouble was uncertain; it had been Saturday night, and the parents were not at home when the children went to bed, but it seems that the children had eaten their midday meal in the usual way, and, though not hungry for tea, had been out of doors in the evening till 7 o'clock. When I reached the house within a few minutes of being called the elder boy was dying, obviously from some very acute intoxication. He had passed from the delirious to the comatose state. The temperature was 104°, the pulse very rapid and irregular, and the breathing irregular. There was a large evacuation of the bowel just before his death at 1.30 a.m. The younger boy was not in such an advanced state of toxaemia, and after the bowel had been thoroughly cleaned out he gradually came round.

A post-mortem examination of the elder boy revealed a condition of acute toxaemia affecting principally the pancreas, liver, and kidney. An organism was found in the intestine and colon which was classed by the bacteriologist as *Bacillus dysenteriae* γ of Hiss. The blood of the brother agglutinated this bacillus.

There seems little doubt that the general epidemic was caused by the same bacillus. With the occurrence of the fatal case it began to abate, and after a week or ten days no more cases appeared. The weather was now decidedly cooler. The interest in this epidemic lies in the widespread distribution in a community of an infection which, though so mild in its general effect as to give rise to no concern, could in an exceptional case cause death in a few hours. The specific causal organism is also of interest.

FOREIGN BODIES IN AN APPENDIX LYING IN A RIGHT INGUINAL HERNIA

A man, aged 60, was admitted into the Bedford County Hospital on May 11th, 1919, for radical cure of a right inguinal hernia. At the operation the appendix was found in the hernia, and as it was enlarged and felt very hard, it was removed. On opening it the following foreign bodies were found: 12 shot, 11 pieces of flattened lead which were evidently shot, a number of minute fragments of lead, 12 hairs (possibly from rabbits or hares), 2 fragments of egg-shell, and 4 threadworms.

The man was a smallholder, and was very fond of ground game. He had never had any symptoms of appendicitis, and there were no signs of inflammation.

Reports of Societies

THE PRACTICE OF INDIVIDUAL PSYCHOLOGY

LECTURE BY DR. ADLER

At a meeting of the Medical Society of Individual Psychology, held in London on January 16th, Dr. ALFRED ADLER of Vienna gave an address. Dr. O. H. WOODCOCK, who presided, explained that this society devoted itself to the individual psychological approach to the problems of medicine and surgery; it was thus the direct continuation of the teaching of Hippocrates, who dealt with the individual rather than with the disease. The two requisites for the pursuit of Adler's method were courage and honesty. It required no little courage to tell a neurotic patient that his illness was a self-deception. But courage and honesty were equally required of the ordinary practitioner; he would not progress by giving to the patient's condition the name of a disease, or by putting the blame on some possibly inoffensive micro-organism.

Dr. ADLER began his address at 8.40, and ended it abruptly, leaving much untold, at 10.50. He had been given, on entering the room, the notes of an actual case of neurosis, and his deductions or "guesses" from point after point as the case-history was developed were most engrossing. He provided, in fact, a demonstration of his method of individual psychology applied to a case the details of which, in writing, had only just been placed before him.

The lecturer began by remarking that both general and special diagnosis were as necessary in psychology as in any other branch of medicine. In individual psychology there was continually presented a situation in which a person was confronted with a certain problem or difficulty he was unable to overcome. The varieties and deviations occurred according to the manner of the patient's strivings or attempts at escape. The point for the psychologist was to discover just where the patient was not prepared to meet a particular social demand, because he lacked the right degree of courage or self-confidence, or was unable to co-operate. The circumstances of early life and the previous behaviour had to be investigated in order to explain this lack of preparation, this inability, this maladjustment. The case presented to him was that of a woman, aged 31, eight years married, with two children —boys—aged 8 and 4. The husband was in poor circumstances; he was an ambitious man who had suffered humiliation because he was prevented from securing a better form of employment by reason of a war injury. Using what he called the sharp eye of the individual psychologist, Dr. Adler immediately presumed that the husband's conflict was reflected in his family life. Unable to satisfy his ambition outside, he would endeavour to satisfy it within his home by striving to rule or "boss" his wife and children. With his ambitions the wife had little sympathy, and therefore there was family dissension. It appeared that the wife suffered from certain phobias, notably the fear of death, and at the time she came for treatment she could think of nothing else. She had been a careful housewife, with an almost obsessional hatred of dirt; she appeared to have a compulsion-neurosis with regard to cleanliness. Evidently this was a mixed neurosis, for the usual cases of wash-compulsion neurosis were not associated with fear of death. She was evidently a woman who could not co-operate, who was occupied only in thinking of herself, with the result that some of her duties and responsibilities would be neglected. Cleanliness was an admirable trait, but if a woman focused her whole being on cleanliness, it meant that she could not co-operate. It was the same with a mind focused on health or any other thing excellent in itself: the obsession disturbed the harmony of life; it involved a certain distortion of life. This patient, however, now began to show neglect in precisely these respects of cleanliness and tidiness; she had broken down and given up the struggle. Dr. Adler mentioned that he had never seen any persons so dirty as those who had suffered from wash-compulsion neurosis; they always appeared to get themselves soiled in situations where others kept clean. In this case, perhaps, it was a step nearer to psychosis. The fear of death was apparently related to definite knife-phobia. Probably this woman had a concealed animus against her children, whom—or one of whom—she had not wanted. There were also suicidal as well as homicidal tendencies. These were all indications of a person not trained in co-operation. Suicide, said Dr. Adler, was in a certain sense always an accusation or a revenge, as also was homicide. The aggressive feelings of this woman towards other people were shown in various ways. She experienced at times an overwhelming wish to hit her husband or anybody else who had annoyed her, and she was very sensitive to affront; such sensitiveness indicated the feeling of being in a hostile country. She was always experiencing and sensing the enmity of her environment. She really believed herself constantly in a hostile situation, and expected to be attacked and humiliated. These characteristics had of late extended in two directions. On the one hand, she experienced at times a strong desire to hit any casual stranger in the street; she had to be carefully watched, and her husband had to accompany her when she went out. She had, so to speak, by this development of her neurosis, given him rules which he must obey. He became a husband under command; he was required to assume responsibility for her, and she utilized and exploited him. She also had a homicidal feeling towards her younger son, aged 4, and this was so intense at times that again her husband had to be carefully on guard. It was probable, said Dr. Adler, that from the beginning this woman had nothing more in her imagination than to make this man a slave. Perhaps she would have been wholly satisfied with the husband's submission, but the husband, too, had been ambitious, and would not submit. But now, by this strange route, she had conquered and subjected her husband, who was in constant attendance on her. In fact, said Dr. Adler, she had created a masterpiece of art. In talking with her he would praise her cleverness, and explain to her that her goal all along had been to rule, and now she had reached it. In this devious way she had made her conquest.

The earlier history of the case showed that definite neurotic strains had been in existence for many years, but had been accentuated since marriage. She had found herself up against the three great problems: the social problem, how to behave to others; the occupation problem,

how to be useful in one's work; the marriage problem, how to co-operate with a person opposite in sex. If since marriage the symptoms had become accentuated, it was a sign that she had not been prepared for marriage. The heredity factor did not interest the individual psychologist particularly; it was not very interesting to him to hear of a crazy aunt or a drunken grandmother. The family history of this woman, however, showed neuroses on both sides. The father was a rough man; he suppressed and maltreated his children, who lived in dread of him. The girl was in childhood guilty of occasional cruelty to her younger brothers and sisters, and these acts of cruelty had been followed by regret. Dr. Adler believed that psychology should not take too seriously these feelings of regret after wrong action. They were common in problem children, who after some wrong-doing were full of regrets before they did the same thing again. Obviously this was mere smartness; if their acts of wrong-doing were continuous they would be intolerable, and strong action would be taken against them. The regret experienced in melancholia, for example, Dr. Adler believed to be no more than a trick. It was interesting to notice that this girl was the second child; some statistics from America showed that among delinquents second children were in the majority. Dr. Adler, however, did not explore the reason for this curious discrimination. The woman had some degree of goitre in childhood, from which she recovered. Very often there was a certain degree of organic imperfection in these cases. A murderous attack was made on her on one occasion by her father; she ran away and spent the day in a graveyard; her fear of death being connected possibly with this experience. Her courtship had been a chequered one. Her fiancé was a cripple, and probably her determination to marry him was due to the same constant desire to assume a dominating role. That was the reason why women of dominating instincts often married the physically crippled, the weak-willed, or drunkards, or men of lower social standing than their own. The motive was not pity, nor a desire to make new men of them; it was the desire to dominate. Definite suicidal feelings started when the patient found herself pregnant before marriage. Pre-marital relations often had an adverse psychological effect in the subsequent life.

The narration ended with the statement that this woman, the subject of these phobias and mad impulses, had been at length taken by her husband to a doctor, who diagnosed nervous dyspepsia, and recommended that all her teeth should be extracted. To this, after some hysterical outbursts, she submitted; sixteen teeth were taken out, and there the story ended. Owing to the lateness of the hour Dr. Adler had to break off his interesting analysis, and the treatment which he himself would have carried out had to be left to the imagination.

Dr. F. G. CROOKSHANK moved a vote of thanks to Dr. Adler for his delightful exemplification of his methods. He could vouch for the fact that until arriving at the meeting Dr. Adler had no idea what was the nature of the case to be submitted to him.

Dr. W. LANGDON BROWN, seconding the vote of thanks, said that this was the first generation that had seriously tried to study the science of human relationship. Once something about the science was known, the art had to be practised. He had always thought that of all the systems placed before the profession, Dr. Adler's was the one which came most into contact with the work of the practising physician in general medicine; it was not nearly so remote from ordinary life as some of the other schemes. The materialistic physician of the past generation never seemed to recognize the fact that the patient had a mind or imagination; and some psychologists now seemed to forget that the patient had a body which could suffer. Dr. Adler, however, never forgot that, and it was because he combined these two aspects of life in unity that the speaker believed his method would prove of very great practical importance in the future.

MANAGEMENT OF PREGNANCY, PARTURITION, AND THE PUERPERIUM IN TUBERCULOUS WOMEN

The Section of Obstetrics and Gynaecology of the Royal Society of Medicine combined with the Tuberculosis Association on January 16th for a discussion on this subject. The chair was taken by Mr. EARDLEY HOLLAND.

Dr. GEOFFREY MARSHALL, in opening for the Tuberculosis Association, said that the first question which had to be asked and answered was whether pregnancy in a tuberculous woman should be allowed to proceed to full term. If allowed to proceed, what effect was the pregnancy likely to have on the pulmonary disease? It seemed to have been the general opinion of the old writers, including Sydenham, that pregnancy was beneficial to the disease in the lung, but in more recent times the view of Osler and others had prevailed, that the effect in such cases was more likely to be disastrous. The pendulum was now swinging to the neutral position. In a French series of 52 cases of tuberculous women who became pregnant, 85 per cent. were said to have been made worse by the pregnancy. Dr. Marshall submitted results in 25 of his own cases, which were only slightly better. Most experienced physicians dreaded the onset of pregnancy in tuberculous women. If, however, when the patient first came under observation, her pregnancy had reached the fourth month or later, artificial termination was seldom advisable. When the pregnancy was at an early stage a better guide than the condition of the pulmonary disease was the tuberculous history of the case. His own view was that in those in whom the disease had recently become quiescent, and in those in whom it had only recently become active, it would be difficult to justify an attitude of non-intervention; but where the disease was chronic, and had already lasted a considerable number of years, he seldom found that pregnancy had any disastrous effect. In advanced cases of the disease the actual pregnancy did less harm, but neither the strain of an anaesthetic nor any incidental operation was well borne. Physicians were afraid of anaesthetics in cases of pulmonary tuberculosis, and this had much to do with their reluctance to employ surgical measures to aid the delivery of the child. He had noticed that some of the worst cases of acceleration of the pulmonary symptoms were those in which the pregnancy was allowed to proceed to full term and in which anaesthetics or forceps had not been used. On the question of suckling the child, if the mother had gone through the pregnancy and parturition without disturbance of the pulmonary disease, the puerperium was not likely to bring about any notable change, and if the weight was maintained and there was no pyrexia, he usually offered no objection to nursing by the mother.

Dr. MELVILLE HILEY quoted a number of authorities favouring the view that pregnancy in the tuberculous woman generally led to an aggravation of the pulmonary symptoms, to the production of fresh lesions, and to the "flaring up" of lesions which had been quiescent. Tuberculosis of the lung had apparently but little effect on parturition; it rarely caused abortion. Even in cases where the tuberculosis was advanced the labour was easy, and apparently the child was well and almost of normal weight. The trouble was that the pregnant tuberculous patient paid insufficient attention to her general health. There ought to be much closer co-operation between the

ante-natal clinics and the tuberculosis officers. It was also too frequently the custom in many sanatoriums to keep tuberculous women in the establishment until they were approaching term, then to discharge them to their homes so that they were lost to medical knowledge until the disease took a graver form. Every effort should be made to render the actual labour as painless as possible, for pain meant the output of much energy. He also thought that for the sake of both mother and child lactation should be forbidden.

Mr. ALEC BOURNE drew attention to the striking diversity of opinion on this matter, both as to the effect of pregnancy on tuberculous disease and as to the treatment which should be adopted. Probably the chief reason for the difference was that no one had sufficient experience of both aspects, so that opinions were biased. A feeling prevalent in Germany was that pregnancy had a noxious influence on pulmonary tuberculosis, so that termination was a logical procedure. In a series of Stockholm cases, comparing 396 non-pregnant women in varying stages of phthisis with 203 pregnant phthisical women, it was found that in tuberculosis which was dormant and supposed to be healed 2 per cent. of the non-pregnant died within a year, as against 1 per cent. of the pregnant; in advanced cases of tuberculosis 37 per cent. of the non-pregnant were dead within a year, as compared with 46 per cent. of the pregnant. After twelve years' experience of infirmary work his general impression was that pregnant women should be informed that pregnancy was of no consequence when the disease was not apparently active, that it was unfortunate when the disease was active, and that it was disastrous when the disease was advanced. In general, it could be said that abortion had no place in the treatment of pregnancy when associated with phthisis. Lactation during the puerperium must be disallowed, and, wherever possible, the infant removed from probable infection by the mother.

Mr. L. CARNAC RIVETT contended that pulmonary tuberculosis and pregnancy were a serious combination, and quoted various statistics on the subject by different workers. In his own opinion, any woman who was pregnant and had an active tuberculous lesion of the lung should receive full sanatorium treatment during the whole period of her pregnancy and for at least six months afterwards. Usually the presence of a tuberculous lesion did not tend to cause abortion, though the child was generally somewhat small. There seemed to be no special reason for interference with labour, especially as it was not advisable to use anaesthetics in such cases. The tuberculous mother should not suckle her infant.

Dr. JANE WALKER referred to an inquiry she had made in 1926, which revealed that the general trend of opinion was against the artificial termination of pregnancy; it was held to be not only useless, but a danger, to produce abortion in these women. At a discussion since on a similar subject at Cambridge, the general opinion was that if pregnancy was to be terminated, the method should be that of Caesarean section. With regard to lactation, her own view was that for the mother to nurse her baby was better for both. During gestation it was agreed by most of her correspondents that the pregnant tuberculous woman should be treated as if she were not pregnant.

Dr. MARGARET SALMOND exhibited tables of figures concerning a series of tuberculous mothers dealt with at the Royal Free Hospital. It was unwise to mix the tuberculous and non-tuberculous patients; the ideal was to have a special small ante-natal ward, a labour ward, and a lying-in ward and nursery for those with the disease. If the latter was active there was little point in inducing abortion after sixteen weeks, as tuberculosis was as much aggravated by abortion as by going to full term.

Dr. VERE PEARSON remarked that pregnant tuberculous patients did very well under sanatorium treatment, though mothers generally showed objections to being in a sanatorium for delivery. Dr. F. H. YOUNG said that in the last four and a half years he had had 120 women undergoing artificial pneumothorax. Eight had become pregnant, and in five the pregnancy was detected early and terminated artificially; in three it was detected late, and allowed to go on. In no case did the tuberculosis seem worse after pregnancy.

Professor LYLE CUMMINS spoke on the question of marriage of tuberculous women, remarking that statistics indicated that the health of the married was superior to that of the single, probably because the married woman had the shelter of a home, and was spared the struggle for a living.

Dr. GEOFFREY MARSHALL, in his reply, said that there was little evidence that the milk of a tuberculous mother contained tubercle bacilli. He allowed the poor tuberculous mother to nurse her child, unless she showed evidence that the strain was too great.

MALIGNANT DISEASE OF THE LARGE INTESTINE

A meeting of the West London Medico-Chirurgical Society was held on January 9th, with Dr. HAROLD SANGUINETTI in the chair.

A discussion on malignant disease of the large intestine was opened by Mr. GORDON TAYLOR, who said that cancer of the alimentary tract was responsible for half the total number of deaths due to malignant disease, and among malignant growths of the large intestine three out of every four were to be found in the last two feet. Half-hearted surgery was to be avoided in these cases, and ruthless resection offered the best hope of cure; a surgeon with a high operation mortality rate could usually boast of more cures than another with a low one. Considerable advantage resulted from preliminary drainage, especially in obstructed cases; the infection of the neighbouring glands was reduced, and hence the subsequent resection was safer. In disease of the ascending colon preliminary anastomosis of the ileum and the transverse colon was valuable, and in one form of operation the peritoneum was sutured in such a way at the first stage as to make extraperitoneal removal of the diseased part of the gut possible at a later date. Even where obstruction was only partial he believed in a two- or three-stage operation. Blood transfusion before operation was useful in all cases where there was bleeding, even if occult blood only was found. In elderly patients with arterio-sclerosis there was always danger of thrombosis of vessels, and he preferred to avoid the use of crushing clamps. A flank incision was preferable to one in the mid-line, and he always drained the wound. In rectal cases the abdomino-perineal operation was the treatment of election. Unfortunately many patients were unfit to stand the shock, and in these the perineal route only must be used. He performed the abdomino-perineal operation in two stages, beginning with a left iliocolostomy; at the second operation the rectum was freed by the perineal route and eventually removed through the abdominal wound. Another method, which might be called the "perineal-abdominal" operation, consisted of a perineal incision and removal of the coccyx; the rectum was freed and removed through an abdominal incision. The introduction of radium into the mesocolon or rectum was a hypnotic technique on the part of the surgeon; the interests of the patient were better served by radical removal. In growths of the recto-sigmoid region the abdomino-perineal operation was required. Attempts had been made in France to preserve the

anal sphincter in new growths of the large bowel, by bringing down the upper segment of bowel and suturing it to the lower, but this accentuated the danger of recurrence, and was to be regarded as a retrograde procedure while the knife was our chief refuge.

Dr. C. E. LAKIN spoke of the differential diagnosis of malignant disease of the large intestine, and described cases in which (*a*) diverticulitis, and (*b*) stricture following amoebic ulcer and associated with amoebic abscess of the liver, had been respectively mistaken for carcinoma of the bowel; while in a case of pulmonary tuberculosis and another of supposed diverticulitis, unsuspected growths had been found post mortem.

Dr. S. L. BAKER referred to the pathology of pre-carcinomatous conditions of the intestine. He was able to show slides of an adenomatous thickening of the intestinal mucosa with a proliferation of the cells lining the tubules; from such an adenoma he thought a tumour might probably arise, not in a few cells only, but over the whole area, and foci might be multiple.

Dr. PARRY MONKHOUSE thought considerable relief in squamous-celled growths of the anal region might be obtained from radium. He would not recommend its use for columnar-celled growths of the rectum, because results were too variable. Radium sometimes relieved the symptoms in inoperable cases.

Mr. W. B. GABRIEL emphasized the value of simple clinical methods in diagnosis. The history was of great importance, and repeated examinations often led to the detection of signs at first missed. The barium enema allowed many fallacies; it might run through a stricture or obscure a small growth, and a negative result from this method of examination should not be regarded as final. For growths of the rectum the abdomino-perineal operation was the ideal treatment, since a large portion of bowel could be removed in order to prevent upward spread; only 6 to 8 inches could be removed by the perineal operation. At St. Mark's Hospital they were able to claim a five years cure in 48 per cent. of cases from the abdomino-perineal operation, with an operation mortality between 10 and 17 per cent. The disadvantage of a two-stage operation was the danger of local cancer implantation in the abdomen from the resected bowel. The perineal-abdominal operation was valuable in cases unsuitable for the abdomino-perineal one. He usually performed his preliminary colostomy under a general anaesthetic, and the second operation under avertin and spinal anaesthesia. Radium he had found to be bitterly disappointing.

Dr. H. H. MILLS questioned whether operation was desirable after a certain age, and described a patient, aged 95, with a distended abdomen and obstruction of lymphatic drainage of the legs, who had persisted in this condition for eight years, while still ruling her household with a rod of iron.

Mr. W. T. WARWICK said that few attempts had yet been made to grade tumours of the large intestine. The St. Mark's Hospital grouping was anatomical, and depended on the degree of spread through the walls of the bowel. At the Mayo Clinic the tumours had been divided pathologically into four groups, according to malignancy, and the percentage of cases in which metastases occurred was found to increase directly with the malignancy of the tumours; 75 to 80 per cent. of the cases fell into the second and third groups. In the first group the tumour cells resembled those of the bowel mucosa; in the second group they were larger, but contained the same proportion of mucin; in the third group they were longer, contained less mucin, and the acinous arrangement was slightly irregular; in the fourth group the acinous arrangement was almost non-existent. Those in the fourth group progressed so rapidly that operation was probably never effective. Clearly some form of grading which combined the anatomical and pathological characters of the growths was desirable.

Dr. GERALD SLOT asked what was the value of a blood count in these cases when anaemia was marked. Cells like megaloblasts were sometimes found which might lead to confusion with pernicious anaemia. He said he would also like to know what value was placed on treatment with heavy metal salts. He had seen cuprase and a selenium preparation used in two inoperable cases with apparent relief of symptoms.

Dr. STUART-WEBB pointed out the fallacies of the barium enema, and the CHAIRMAN referred to the difficulties of the general practitioner in obtaining special examinations at a reasonable cost for middle-class patients. He thought it possible that in some cases removal of the tumour reduced the resistance of the patient to further spread.

INSOMNIA

The Brighton and Sussex Medico-Chirurgical Society met on January 8th, the president, Mr. H. N. FLETCHER, being in the chair.

Lieut.-Colonel GEORGE BIDIE, I.M.S.(ret.), in the course of a paper on insomnia, dealt primarily with some points in the physiology of sleep, beginning with Altshuler's definition of sleep as "The expression of the work of an instinct, strengthened by habit, and regulated by conditioned reflexes." Phases in the development of the sleep instinct from the lower animals to man were described. Stress was laid on Pavlov's theory of sleep —namely, that internal inhibition was a conditioned reflex productive of a state of inactivity, and that sleep was an accumulation of internal inhibitions radiating over the entire cerebral cortex. The physiological accompaniments of sleep were discussed, as well as the production of experimental insomnia in man and in animals. The daily rhythm of sleep, dissociation in sleep, Pavlov's experiments, the effect of drugs on conditioned reflexes, calcium metabolism, the influence of pathological conditions, the role of hypnotics, and the regulation of sleep by the grey matter of the brain, were dealt with in turn, after which the speaker proceeded with his main theme. He said that, as the physiology of sleep was unknown, the causes of insomnia could not be classified on a scientific basis, but we could differentiate cases, from the view-point of treatment, into (1) those associated with various stimuli founded on physical changes, (2) emotional states, or (3) grave psychotic conditions. In cases of persistent insomnia, the habit of sleep had been broken, and the patient had lost confidence; to these were added fears—all powerful factors in maintaining the condition. Sleeplessness should be regarded merely as a symptom, and every endeavour made to unearth the primary cause. The treatment of insomnia called for a thorough investigation of the physical and mental functions of the patient. Lieut.-Colonel Bidie stressed that the aim should be to restore the patient's confidence, and that every effort should be made to reform the habit of sleep. After enumerating the principal factors of insomnia and the effects of sleeplessness, the lecturer discussed the clinical manifestations of disordered sleep, and their treatment. He emphasized the importance of the selection of an appropriate drug, its early administration and adequate dosage, and its continuance until the patient's health and sleep were restored. One important problem had to be decided—whether in serious cases of insomnia the patient should be treated at home or sent on a holiday free from all anxiety. In the event of it being a case of severe psychosis or one requiring prolonged psychotherapeusis, institutional treatment might be necessary. The position of psychotherapy and the importance of suggestion were discussed, also the careful apportionment of rest, work, and play. Lieut.-Colonel Bidie concluded by making a survey of present-day hypnotics, with a summary of the opinions on their continuous administration and the effects on excretory organs, especially by drugs of the barbitone group.

Reviews

THE PLATING OF FRACTURES

The book on osteosynthesis[1] of Dr. DUPUY DE FRENELLE is, in one respect, unique. His work is preceded by a critical analysis of twenty-three pages, by that distinguished advocate of the open treatment of fractures, Dr. Lambotte of Antwerp. We thus have not only an exposition of Dr. Dupuy's opinions and methods at length, but also an extremely interesting and instructive essay on them, in which Dr. Lambotte frankly expresses approval and disapproval as the case may be, and at the same time provides a summary of his own views. This work may profitably be compared with the much less ambitious *Primer on Fractures* of the American Medical Association, which is discussed elsewhere in this issue (p. 147), as the two publications represent widely separate points of view. Unlike the primer, Dr. Dupuy's book does not include emergency treatment, and he has no use for external splints, relying as he does on metallic splints placed in contact with bone, but we may presume that he would recognize the necessity for some first-aid support.

Dr. Lambotte asks why it is that the method of treating fractures with plates, screws, etc., has been so long discussed and is still not accepted by all surgeons as a routine treatment. He answers the question by pointing out that it is the most difficult kind of surgery, and, although capable of giving marvellous results, it exposes the patient to serious disasters if the technique is faulty. These considerations should not, however, be allowed to prejudice us against the method, but rather should stimulate us to perfect our technique. No doubt the surgeon who treats fractures by open methods must be a particularly skilled handicraftsman, even if he does not, like Dr. Lambotte, make his own instruments, but we think that there is more in it than that. In the clinics of Drs. Lambotte and Dupuy there is every appliance, all the trained assistance that may be needed, and the practice of asepsis is carried on to its greatest perfection. The majority of simple fractures cannot be treated in such ideal conditions, however, nor can the surgeons who must perforce treat them have the same degree of skill or a tithe of the experience of these leaders in osteosynthesis. Even if surgeons were all convinced by the arguments of Lane, Lambotte, Dupuy, and some others they could not safely attempt to follow their practice as a general rule. In those cases—and they are not a few—in which open operations are necessary, a knowledge of the opinions expressed by Dr. Lambotte, and of the methods described and so well and clearly illustrated by Dr. Dupuy, will be of the greatest value. It is not enough to decide rightly to apply a plate or a wire girth (*cerclage*) to the fragments; it is all-important to choose the right kind of metallic supports and those of the right dimensions. Too often a short plate is expected to fulfil the duty of keeping the ends of the fragments of a femur in position, when a better knowledge of mechanics and the technique of joinery would discourage such expectation. Dr. Lambotte lays down as a general rule that for diaphyseal fractures the plate should be at least five times as long as the diameter of the bone. In this connexion he remarks: "My plates, such as are sold commercially, are nearly all ill made; they have nothing of mine about them but the name. Those which I use I make myself."

It is impossible within the bounds of a review to go further into the questions raised by this interesting book. Those who are about to undertake bone-plating or grafting will be well advised to consult it. Dr. Dupuy's figures are on a large scale, and are exceptionally clear and explicit.

TUBERCULOSIS IN CHILDREN

We opened Dr. J. A. MYERS's book, *Tuberculosis among Children*,[2] with anticipation of great pleasure and profit, but at its closing there was a definite sense of disappointment. This is not an adverse criticism of Dr. Myers, or even, in some sense, an adverse criticism of his book, but rather a prayer that he should allow us a larger and more detailed participation in his great experience of this subject. The relation of childhood tuberculosis to adult tuberculosis is now considered to be all-important, and is being intensively studied in every civilized country. America seems more able to find the money, the ardour, and the docility among her citizens for large sociological experiments than any other country, and the Lymanhurst School for Tuberculous Children in Minnesota, of whose medical staff Dr. Myers is the chief, is one of these. He has a great deal he could tell us, but he has used this comparatively small book of two hundred pages to drive home one important fact—that tuberculosis in children and adolescents is due nearly always to direct exposure, and that the main danger lies in repeated or continuous exposure. If one realizes from the start that this is the main lesson of the book it can be read with great pleasure and profit, and with no disappointment.

In the process of developing his argument the author gives us glimpses of other very interesting and important aspects of tuberculosis in childhood and much terse teaching. But from beginning to end he reiterates that we must search for and eradicate the source of infection. The book is introduced by A. K. Krause, and is divided into three sections: tuberculosis in infancy, tuberculosis in childhood, tuberculosis in the "teen age" (not a very pleasant new phrase). There are some excellent *x*-ray plates, and—a wise decision—very few statistical tables. Each chapter finishes with a useful summary and a full bibliography. A twelve-page chapter on tuberculous meningitis, a sixteen-page chapter on surgical tuberculosis, and a six-page chapter on chronic non-tuberculous basal pulmonary disease in children, by collaborating authors, could be omitted with advantage; also, perhaps, one of fifteen pages by the author on other tuberculous lesions in childhood.

The book is well produced. Dr. Myers's style is not an easy one to read, but that is a small matter. The hope may be expressed that this is to be one of a series from him, and that its successors will be more direct and more condensed.

PATHOGENIC MICRO-ORGANISMS

The third edition of KOLLE and v. WASSERMANN's Handbook of Pathogenic Micro-organisms[3] continues to appear seriatim; references to the earlier volumes have appeared in these columns, the last being in the issue of May 10th, 1930 (p. 866). We have now received Parts 42, 46, and 47 of vol. vii, Parts 44 and 45 of vol. viii, and Part 43 of vol. x. The first of these contains a descriptive account of the pathological spirochaetes by Professor P. Mühlens of Hamburg, and also a note on the saprophytic spirochaetes by Dr. St. Zurukzoglu of Berne. Dr. R. Ruge of Dresden contributes a full account of the bacteriology of malaria, and Professor G. Giemsa of Hamburg deals with chemotherapy. Part 46 is mainly devoted to the trypanosomes, Professor W. Nöller of Berlin supplying a comprehensive survey of these organisms and the diseases they cause. Professors P. Manteufel and M. Taute of Berlin review human trypanosomiasis, and Professors W. Zwick of Giessen and P. Knuth of Landsberg

[2] *Tuberculosis among Children.* By J. Arthur Myers, Ph.D., M.D., F.A.C.P. London: Baillière, Tindall and Cox. 1930. (Pp. xiv + 208; 43 figures. 16s. net.)

[3] *Handbuch der pathogenen Mikroorganismen.* Begründet von W. Kolle und A. v. Wassermann. Dritte, erweiterte Auflage. Jena: G. Fischer; Berlin und Wien: Urban und Schwarzenberg. 1930.

give an account of the manifestations of this disease in animals. Part 47 contains an interesting description of leishmaniasis by Dr. L. E. Napier of Calcutta, and a general account of protozoal diseases by Professor V. Jollos of Berlin. Two Parts of vol. viii have also now been published; this volume relates more particularly to certain special diseases caused by micro-organisms. In Part 44 Professor H. da Rocha Lima of Brazil writes about verruca peruviana (Oroya fever), and Dr. E. Lauda of Vienna discusses its specific organism, *Bartonella bacilliformis*. Typhus fever is considered by Professor R. Otto and Dr. H. Munter of Berlin; Rocky Mountain spotted fever by Professor F. Breinl of Prague; and quartan fever by Professor H. Werner of Berlin. The diseases attributable to pediculi are reviewed by Professor A. Hase of Berlin.

Part 45 of vol. viii has special claims to attention in view of a detailed description in it by Professor R. Doerr and Dr. E. Berger of Basel of herpes zoster and encephalitis, with a note on post-vaccinal encephalitis. The Rickettsia group of micro-organisms is the subject of an article by Professor da Rocha Lima of Brazil. The other contributors to this Part are Professor R. Kawamura, who writes on tsetse infections, and Dr. O. Hartoch of Leningrad and Professor Schürmann of Bochum, who deal with infections of obscure etiology, and record some investigations on measles. In Part 43 of the tenth volume Professors O. Teutschlaender and R. Werner of Heidelberg discuss the various methods of investigating tumours. The remainder of this Part is devoted to the establishment and organization of laboratories, Professor L. Haendel of Berlin dealing with this subject generally, while Professor R. Doerr of Basel restricts himself to mobile bacteriological laboratories. The practical outlook of the several authors is as pronounced and helpful as was the case in the previous volumes of this useful, though increasingly bulky, handbook. The illustrations are of a very high order, and the only complaint that can reasonably be made is of the length of the series, and the spasmodic appearance of its various Parts. As a work of reference the *Handbuch* certainly merits great praise.

BIOLOGICAL ASSAY

The principles, methods, and problems of biological assay[4] form the subject-matter of an interesting and authoritative monograph by Dr. JEANNE LÉVY. Up to the present, according to Professor Tiffeneau, who contributes a preface, no work has appeared in the French language covering quite the same ground, and he believes that Dr. Lévy's monograph should encourage the introduction of compulsory biological assay by the French Government.

When in the middle of the nineteenth century workers began to study drugs by the method of chemical assay, an important step was taken in the development of accuracy in therapeutics. But to many substances the method was inapplicable, or its application failed to yield accurate enough information, and gradually methods of biological standardization were evolved. With the new method came new problems, one of the chief of which was to make proper allowance for variation among the animals used for standardization. One by one these problems are being solved, partly by breeding standard experimental animals, partly by adopting statistical methods, and the result has been a discovery of many unsuspected imperfections in the work of the organic chemist. The variations in potency that biological assay has proved to exist between different samples of such organic arsenical compounds as neosalvarsan are well known; less familiar is the fact that it has revealed similar variations in much simpler synthetic substances—for example, mercurochrome and novocain.

Lévy's monograph falls naturally into three parts. The first deals with the general principles of biological assay; the second with the methods recognized by the League of Nations Committee; and the third with methods that have not yet received official recognition, including a number that have been evolved in the pharmacological laboratory of the Faculty of Medicine, Paris. Of special interest in the third part of the book are the author's descriptions of new methods for the standardization of local anaesthetics. The work is well illustrated, and the technique of the various processes is clearly set out.

TREATMENT OF GAS CASUALTIES

The *Manual of Treatment of Gas Casualties*[5] is a War Office publication, issued by command of the Army Council. It therefore appears with all the importance and authority of an official document. In the event of fresh wars it is almost certain that the number of temporary medical officers serving with the forces will be greatly augmented. It is no less obvious that in the presence of large fleets of aeroplanes this country will be just as vulnerable to attack from the air as any other European country. That the greatest part of such an attack will be conducted by means of gas seems equally evident. Under such an attack the civilian population will be the first to suffer. From the nature of their employment in their daily life, civilian doctors will have little knowledge or understanding of gas warfare, while their comrades in the Regular Army will have to depend mainly on theoretical principles rather than on actual experience in dealing with gas cases. Yet on the ability of medical officers to bring rapid and appropriate treatment to casualties from this method of offence will largely depend our success in minimizing losses.

This book, with less than a hundred pages, has been issued in portable form in order that information of practical value may be available in the field. The nature of anti-gas defence and the factors governing the use of gas are carefully described, along with short accounts of the gases liable to be encountered by troops in the field and the civilian population. As may be supposed from previous experience with publications from the same source, the manual deals clearly and concisely with the various aspects of this important subject. In these days, when the belief is widespread that all questions of international disagreement can and will be settled by arbitration, it is not to be expected that such a work will have a wide circulation. To those, however, who fear that war has not been abolished, and who are so old-fashioned as to believe in being prepared, this book can be strongly recommended.

HEART DISEASE

The sixth edition of Dr. E. M. BROCKBANK'S book on *The Diagnosis and Treatment of Heart Disease*[6] follows the lines of the issue of 1923, when considerable alterations and additions were made. In its present form students and younger practitioners should find it of value, as it gives much of the practical detail and explanation frequently absent from current textbooks. It also keeps before them the importance of the clinical examination of the patient, an aspect which is apt to be overshadowed by the more objectively attractive methods of instrumental

[6] *The Diagnosis and Treatment of Heart Disease.* By E. M. Brockbank, M.D., F.R.C.P. Sixth edition. London: H. K. Lewis and Co., Ltd. 1930. (Pp. xvi + 240; 35 illustrations. 7s. 6d. net.)

examination. If the book errs, it is perhaps in the attempt to deduce too much from individual signs. There are a few additional illustrations, but the volume maintains its convenient form and moderate price.

NOTES ON BOOKS

The sixth volume[1] (Kropf- Magen- und Duodenalgeschwür) of the New German Dictionary of Practical Medicine, edited by Professors GEORG and FELIX KLEMPERER, has soon succeeded the fifth, to which we drew attention some months ago. The twenty-one articles contained in the present volume are as follows: goitre, by Dr. A. Kocher of Berne; paralyses, by Professor P. Schuster and Dr. H. Pinéas of Berlin; treatment by liver extract, by Professor R. Morawitz of Leipzig; acute inflammations of the liver, by Professor G. Lepehne of Königsberg; chronic inflammations of the liver and forms of cirrhosis, by Professor F. Rosenthal of Breslau; tumours of the liver, by Professor T. Brugsch and Dr. H. Horsters of Halle; syphilis of the liver, by the same writers; leukaemia and allied diseases, by Professor H. Hirschfeld of Berlin; lichen ruber, by Professor A. Buschke and Dr. W. Curth of Berlin; examination of the cerebro-spinal fluid, lumbar, cisternal, and ventricular puncture, encephalography, ventriculography, and myelography, by Professor K. Eskuchen of Zwickau; pulmonary emphysema, by Professor R. Siebeck of Bonn; pneumonia, by the late Professor M. Matthes and Dr. R. Wigand of Königsberg; cancer of the lung, by Professor O. Rostoski of Dresden; pathogenesis and morbid anatomy of pulmonary tuberculosis, by Professor H. Anders of Berlin; diagnosis and treatment of pulmonary tuberculosis in the adult, by Professor Felix Klemperer; dislocations, by Professor W. Baetzner; lymphogranulomatosis, by Professor H. Assmann of Leipzig; lymphogranulomatosis inguinalis, by Dr. Professor W. Frei of Berlin; methods of examining the stomach, by Professor R. Ehrmann and Dr. L. Dinkin of Berlin; gastric and duodenal ulcer, by Dr. H. Kalk of Berlin; and surgical treatment of gastric and duodenal ulcer, by Professor H. von Haberer of Düsseldorf.

Forty Years with the Aborigines,[2] by the Rev. E. R. GRIBBLE, is a personal record of pioneering missionary work in the backwoods of Queensland and Western Australia. It is a pity that the author has few literary graces, for his flat and rather stilted style is apt to obscure the dramatic interest of the narrative. There can be no doubt, however, of his exceptional courage and strength of conviction in peril and adversity, and it is clear that these qualities have been combined with rare tact and sympathy in his dealings with the natives. Mr. Gribble is convinced that the Australian aboriginal is capable of being educated to a fairly high standard in a suitable environment and with congenial conditions of work. At his mission station at Yarrabah, where an eight-page newspaper was issued monthly, all the printers were aboriginal youths, while the mission dentist, also an aboriginal, was drummer in the brass band, and sacristan and server in the church. He adds that seven full-blooded aboriginals who held the bishop's licence as lay readers were adults and married before they learned the alphabet. Such progress, however, is seriously hampered by alien influences. The author deplores the addiction to opium, which, in spite of Acts of Parliament, is evidently destroying thousands of lives every year in northern Australia. "The opium refuse . . . is all saved by the Chinese, made into small balls, and given to the blacks; this mess is dissolved in water and drunk. I have witnessed mothers giving the vile poison to their infants." There are a few notes about burial customs and native beliefs, but these, unfortunately, are scattered and only incidental. Several of the photographs illustrating the volume are remarkable.

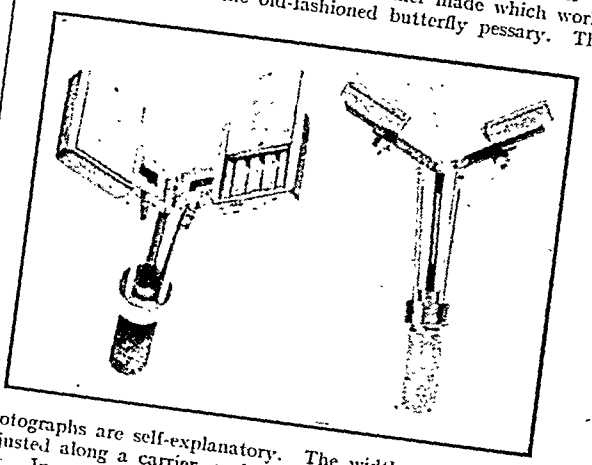
The name of Richet is inseparably associated with anaphylaxis, and therefore the little volume on *Alimentary Anaphylaxis*,[3] which has been written by that distinguished authority's son, collaborating with LAROCHE and SAINT-GIRONS, is to be recommended to those interested in the subject. As Professor RICHET states in a foreword, each clinical case must be studied by itself if one is to obtain a comprehensive idea of the problem, and therefore this treatise should be of assistance to research workers in protein sensitivity when dealing with the individual difficulties of a variable condition.

Preface by Albert H. Rowe. Berkeley, California: University of California Press; London: Cambridge University Press. 1930. (Pp. 139. 9s. net.)

PREPARATIONS AND APPLIANCES

THE MOUNT VERNON HOSPITAL BUTTERFLY RADIUM CONTAINER

Mr. MALCOLM DONALDSON, F.R.C.S., writes: In carrying out the Heyman technique it is not always easy to get the "box" containers "well out into the fornices and to keep them in position. This fact can readily be demonstrated by *x*-ray photographs of the patient during treatment. In order to overcome this difficulty I had a container made which works on the principle of the old-fashioned butterfly pessary. The



photographs are self-explanatory. The width of the wings is adjusted along a carrier, and the boxes are fixed by a small nut. In case of a large crater the wings can be screwed past the right angle, so that the radium lies flat against the sides of the crater. The whole pessary is covered with rubber during use.

The above container was made for Mount Vernon Hospital by Messrs. Johnson, Matthey and Co., Ltd., 78, Hatton Garden, E.C.1.

A SIMPLE HOLDER FOR RADIUM NEEDLES FOR SURFACE APPLICATION

Dr. CRANSTON WALKER (Birmingham) writes: The corrugated paper of commerce consists of corrugated sheets attached to plain sheets so that each alternate corrugation forms a small tube. The fine quality, such as is used for packing chocolates, provides a convenient holder for the superficial application of radium needles. Strips are cut from it easily obtainable from stationers. This paper is a little wider than the length of the needles; it is not necessary to thread the needles; they are inserted into the tubes of the paper at suitable intervals. They may be secured by folding a piece of gummed paper, or adhesive strapping, over each edge of the strip. The corrugated paper containing the needles may be passed through melted paraffin wax; this renders it impervious to discharges and lotions, and without other adjunct secures the needles. By this means is obtained a flexible applicator retaining the needles in a regular arrangement, which is not altered by adjustments of dressings. By holding the paper strip up to the light the needles in it may be counted without being disturbed, and the radium stock audited. The needles are easily released by cutting the paper, or by dropping the strip into boiling water, when the wax melts and the paper soon disintegrates. The resemblance of the loaded strip to a small bandolier suggests a convenient nickname.

British Medical Journal

SATURDAY, JANUARY 24th, 1931

SOME PROBLEMS OF HYDATID DISEASE

The prevalence of hydatid disease in man is difficult to assess accurately, even in countries where it is endemic. Competent observers are convinced, however, that it is increasing in the Argentine and in New Zealand. In our own country, cases are met with and are occasionally reported in the medical literature; and though by no means common, hydatid disease occurs often enough to merit the attention alike of practitioners and the public health authorities. The life-history of the parasite is known. The adult tapeworm, *Taenia echinococcus*, inhabits the intestine of the dog, and the ripe ova are passed in the excreta and conveyed to the human being by food that has become contaminated. In man the cystic stage of the parasite develops, and though the liver and lungs are the commonest sites for hydatid cysts, infestation may occur in any part of the body. The herbivora, as well as man, act as intermediate hosts, and harbour the parasite during its cystic stage. When dogs eat the affected organs of sheep or of cattle the life-cycle is completed; tapeworms develop in the dog's intestine and become a potential source of infection to man and to herbivorous animals. With the common knowledge of these facts, it would seem possible to break the chain of infection and so to stamp out the disease.

Dr. James F. Brailsford's article on hydatid disease in England, published elsewhere in this issue, and accompanied by illustrations on a special plate, is a timely contribution to the subject. Dr. Brailsford has made a special study of the occurrence of hydatid infestation of the viscera of sheep, cattle, and pigs over a series of years at the public abattoirs in Birmingham. He noted that examples of this disease were of daily occurrence in slaughtered animals, and that often the infestation was heavy. It is from such animals that the infection is carried to dogs, since the diseased viscera, though unfit for human consumption, may be eaten by dogs and cats. This is the link in the chain of infection which is likeliest to break if an adequate effort is made by the public health authorities to stamp out the infection. Already, most of the local authorities have by-laws prohibiting the admission of dogs to slaughterhouse premises, but these are not strictly enough enforced. The destruction of infected offal by burning is to be recommended, since when used as manure and spread about the land butcher's offal is easily accessible to stray dogs. In the course of his observations Dr. Brailsford found that some herds were extensively infested, others were free. In the former it should be possible to trace the infection back to some dog on the farm which is a carrier of the tapeworm and disseminates ova in its excreta. Where the carrier is a well-trained sheep-dog treatment by courses of anthelmintics would be efficacious, though less valuable dogs should be destroyed. Since hydatid infection is common in animals bred for food, and does not affect the sale of the meat of the animal, butchers are led by familiarity to neglect its potential dangers. Another cause of indifference may be the comparative rarity of its occurrence in man, but medical practitioners should be aware of the severe nature of hydatid infection when present, and the danger of its life-destroying complications. The period between infection and the appearance of symptoms is so long that lay persons are seldom aware of the risk they run in allowing infected dogs to be the close companions of children. It is, of course, when dogs are closely associated with sheep and cattle, in slaughterhouses or on farms, that hydatid infestation is most likely to occur. In countries where the disease is endemic, stray dogs in towns are affected equally with dogs in the country; but Dr. Brailsford has not found that this is true in England. It would seem, therefore, that in this country a vigorous policy of control in slaughterhouses and farms would lead to the eradication of hydatid disease.

The problems of diagnosis are many. Readers will find a full description of the methods of solving them in Dr. Brailsford's interesting paper. Modern serological inquiry has done much by studying the tissue reactions evoked by the growing hydatid cyst, while Dr. Brailsford's own special subject, radiology, has thrown light on the diagnosis of deep-seated cysts, particularly in the chest. In the natural course of the disease the hydatid cyst continues to grow, producing symptoms by pressure and by erosion of the host's tissues, with haemorrhage or rupture into a hollow viscus or cavity. Interference with its blood supply may cause the cyst to die and degenerate, when it is easily the subject of septic infection. Trauma may rupture the cyst or bring about a curious form of involution, resulting in the growth of daughter cysts within the original. Absorption of the hydatid fluid following rupture is often attended by severe symptoms of shock, anaphylactic in nature. A further consequence of rupture is the spread of the scolices or immature hydatid heads; these, becoming scattered in the peritoneal cavity or in a wound, may later develop into true hydatid cysts—a "secondary" echinococcosis, first described by Dévé and now accepted as a mode of involution of the parasite. The dangers of indiscriminate puncture of hydatid cysts are therefore very real. Drugs, however, appear to have no remedial effect, and surgery is the only method of treatment. Operation should be carried out with due regard to the risks the patient may run, both at the time of operation and afterwards, if the surgical technique be faulty. John Hunter said in his lectures on the principles of surgery, writing of hydatids of the liver: "When known to be a bag containing fluid it may be opened, but I would not be in a hurry to do this."

A. TUDOR EDWARDS: MALIGNANT DISEASE OF THE LUNG

FIG. 1.—Skiagram showing tumour in right lower lobe. Note absence of inflammatory reaction in adjacent pulmonary tissue. (Case 2.)

FIG. 2.—Appearance of chest five weeks after complete removal of right lower lobe of lung. (Case 2.)

A. TUDOR EDWARDS: MALIGNANT DISEASE OF THE LUNG.

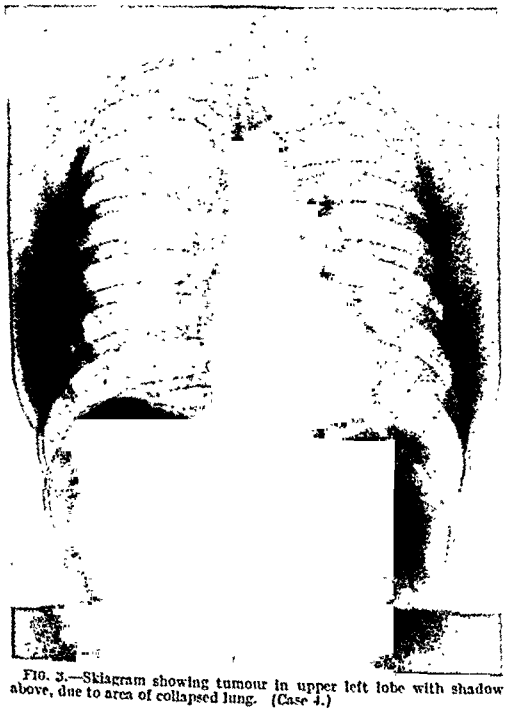


FIG. 3.—Skiagram showing tumour in upper left lobe with shadow above, due to area of collapsed lung. (Case 4.)

FIG. 4.—Skiagram taken two months after removal of carcinoma of bronchus. (Case 4.)

A. TUDOR EDWARDS: MALIGNANT DISEASE OF THE LUNG.

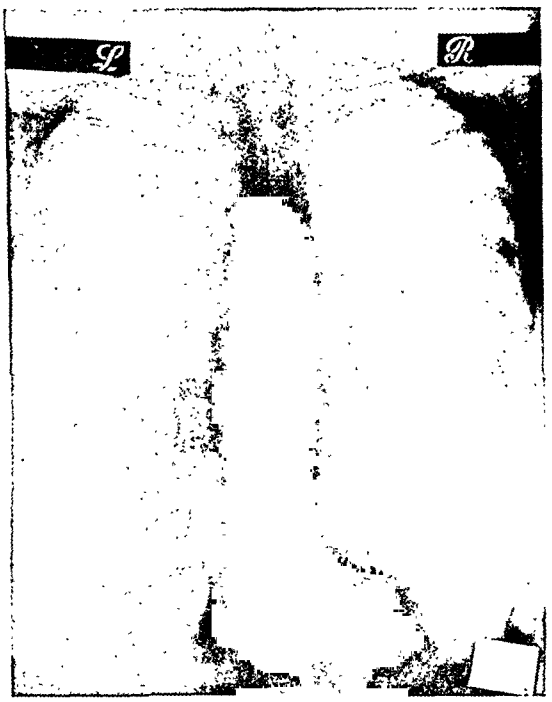

FIG 5.—Shows well-defined tumour at apex of left lung. (Postero-anterior view.) (Case 5.)

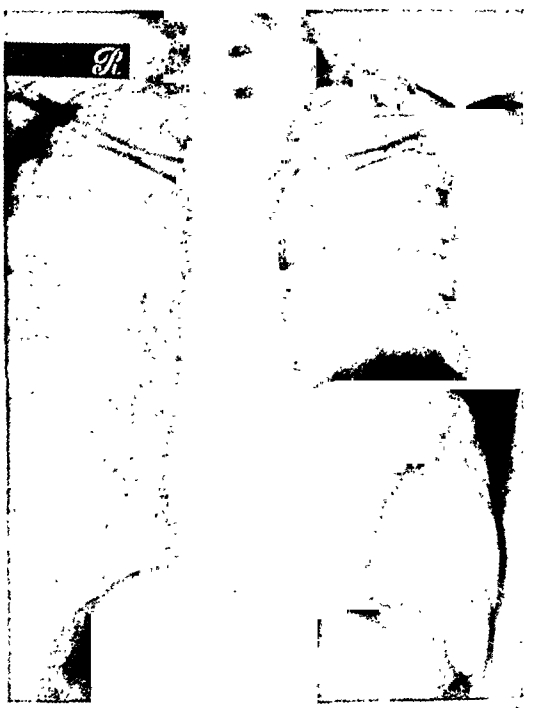

FIG. 6.—Appearance in erect posture after induction of pneumothorax. The weight of the contained tumour has displaced the apex of the lung downwards. (Antero-posterior view.) (Case 5.)

A. TUDOR EDWARDS: MALIGNANT DISEASE OF THE LUNG.

FIG. 7.—Appearance four months after partial pneumectomy. Note the displacement of the mediastinal structure to the left to compensate for loss of pulmonary tissue. (Case 5.)

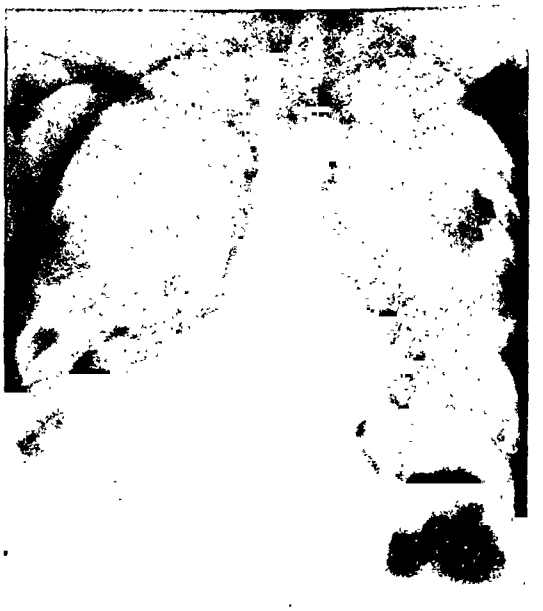

FIG. 9.—Radiograph showing degeneration of a secondary tumour in the left lung with partial evacuation of its liquefied interior.

A PRIMER OF FRACTURE PRACTICE

The problems presented to us in this country by the ever-increasing number of accidents have been confronted with energy and enterprise in the United States, where they are even more formidable than here. Among methods of improving the treatment of fractures the education of the general practitioner, and also of the general surgeon, has not been overlooked. In 1926, at the annual meeting of the American Medical Association, it was decided to present at the annual Scientific Exhibit demonstrations of proper handling of fracture cases. The committee appointed by the Sections on General, Abdominal, and Orthopaedic Surgery to carry out the necessary work included Dr. Nathaniel Allison of Chicago, Dr. William Darrach of New York, and Dr. Kellogg Speed of Chicago. During the next four years (1927–30) these distinguished surgeons were assisted by an Advisory Committee on Fractures, on which, at one time or another, seventeen well-known surgeons served. At four successive annual meetings of the association demonstrations of approved methods of treatment, especially of first-aid treatment, have been given, and so great an interest has been taken in these that no fewer than seven "booths" have been needed to satisfy the demands of members. The number of surgeons who have acted as demonstrators amounts to 137, and the list of their names includes those of many well-known orthopaedic surgeons and exponents of general surgery. These demonstrations were made upon the *corpora vilia* of United States soldiers, lent by the Army Medical Department.

Each year an illustrated folder is prepared, depicting the booths and reproducing the legends which emphasize important maxims. The American Medical Association appears to have profited by the lessons taught by professors of the great transatlantic art of advertisement, and such slogans as "Splint 'em where they lie!" and "It is the doctor behind the splint, and not the splint that counts in the treatment of fracture," seem to have been repeated again and again, until the dullest mental retina must have received indelible impressions of them! The demand for the folders from those who attended the demonstrations, from teachers in medical schools, and from others was so great that it was decided to reprint them all and bind them in one cover, under the title of *Illustrated Primer on Fractures*.[1] The Committee on Scientific Exhibit of the American Medical Association, which has courteously presented us with a copy of the primer, points out that it is not intended as a step towards the standardization of treatment, but rather an attempt to suggest what constitute acceptable methods of treatment. For such a purpose it is well adapted. The outline drawings are clear, and the eighteen injuries chosen for illustration are typical, but we do not know on what principle of selection dislocation of the hip is left out while dislocation of the shoulder is included, unless it be on the ground of comparative frequency. Each plate is accompanied by a short text descriptive of the treatment recommended. The advice given is practical and pithy, and, together with the slogans which are represented as adorning the walls of the operating theatre, they include the essentials for attaining satisfactory results. The list of "splints for the doctor's automobile" includes 1 Thomas leg splint, 1 Thomas arm splint, 6 bass wood splints, enough sheet wadding or cotton-wool, 1 tourniquet, 1 can of ether, bandages, and adhesive tape. The kind of tourniquet and the size of the can of ether are not specified. The supply of splints recommended for the doctor's surgery is naturally on a much more generous scale. It includes material and tools for making and adjusting splints and other appliances for fractures.

Such energetic and persistent propaganda as this primer represents must have an effect, and perhaps a great one, on fracture practice in the United States. Although it makes no pretence of teaching diagnosis or prognosis, yet it wisely insists on the necessity for *x* rays. A manual of this sort would probably be welcomed and would prove of great use in this country. Slight modifications of the original might be required to fit it to British conditions, and we would suggest that its usefulness would be increased without great addition in bulk and cost if Pott's fracture and more dislocations were to be included; but, taken as it stands, it is a very valuable practical guide for the practitioner and those in charge of cottage hospitals.

DIRECT TRANSMISSION OF YELLOW FEVER

The article by Dr. G. C. Low and Dr. N. Hamilton Fairley, printed in the opening pages of this issue, again directs attention to a method of infection with yellow fever which remained unsuspected until the disease had been studied in non-endemic areas, where the possibility of mosquito transmission could be eliminated. Since the pioneer work of the American Yellow Fever Commission in Cuba it has been generally held that this disease is transmitted solely by the bite of the yellow fever mosquito, *Aëdes aegypti* (*Stegomyia fasciata*), but although, as mentioned in our leading article of December 20th, 1930, it is now known that other species of mosquitos may also serve as carriers, there has remained a certain doubt as to the manner in which the various laboratory infections of the past two or three years have been acquired. It was well known that the blood of human patients, and also of monkeys infected with yellow fever, contained a very high concentration of virus, at least during certain stages of the disease; but the experiences of past Yellow Fever Commissions in endemic areas seemed to indicate that there was no danger of the infection being acquired in the absence of mosquitos. Unquestionably cases of infection and death from yellow fever had occurred among the members of these commissions, but such infections were always attributed to the bites of infected mosquitos. The results described by Dr. Low and Dr. Fairley, however, suggest that at least some of these

infections may have been acquired in the course of routine collection and examination of blood from yellow fever patients, for it has not been the general practice to wear gloves when making these tests. In view of our present knowledge of the highly infectious character of blood from yellow fever patients, it is surprising that more of these infections should not have been recorded among the earlier investigators. The explanation probably lies in the fact that the only known method of identifying mild cases of the disease is by means of protection tests in monkeys with the patient's serum, and as this test has only recently been introduced many of these investigators may have undergone unrecognized attacks of yellow fever. The two hospital cases now recorded illustrate strikingly the danger of making any blood examinations on yellow fever patients unless the skin is adequately protected; and, in endemic areas where the disease is prevalent, it would certainly seem to be a wise precaution to use gloves when collecting blood, even if the case is not suspected as being yellow fever.

INDIVIDUAL PSYCHOLOGY

The visit last week to England of Dr. Alfred Adler of Vienna has called attention anew to a form of psychological investigation and therapeutics in which emphasis is primarily laid upon the patient and only secondarily on his symptoms. In a lecture on the structure of neurosis, which he delivered on January 13th before the Section of Psychiatry of the Royal Society of Medicine, Dr. Adler emphasized the importance, as a factor in nervous disorder, of mental tension brought about by the inability to make healthy adjustments to environmental difficulties. This tension manifested itself through defective organs, and as alterations of the endocrine balance, with an excessive sensitiveness and faulty compensations. The presence of an "inferiority complex" was indicated by the struggle to achieve superiority over others in some way or another, and to render them dependent, while insisting simultaneously on being allowed to be dependent on them. In another lecture, which is reported at page 139, Dr. Adler indicated how such a process of maladjustment worked out in a particular case, and how the various symptoms could be explained. This was the first step in devising suitable treatment, which would be directed to the essential cause of the disorder. There would follow a process of re-education with a view to replacing passive dependency on others by an interest in active co-operation with them. Such a readjustment of the emotional and mental outlook would result in the disappearance of organic and psychic symptoms, now no longer necessary to the patient as a defence against painful situations in life. In his scheme of psychological analysis and treatment Dr. Adler recognizes the importance of taking into account organic inferiorities as well as psychological failures of adjustment, and so the basis of his approach to the rectification of nervous derangements is broader than that of certain other schools. Whether it is sufficiently broad to be fully comprehensive is doubted by some, but at any rate there is in it a measure of "sanctified common sense" which has the very important additional merit of being scientific.

HEALTH OF COTTON OPERATIVES

Dr. Dearden, in his Milroy Lectures delivered in 1927, dealt fully with sickness among operatives in Lancashire cotton-spinning mills with special reference to card-rooms, and showed by a very accurate morbidity table the chief factors affecting the health of the cotton operative. Later in the same year the Home Secretary, as a result, we believe, of representations made from the operatives' union, appointed a Departmental Committee to investigate the whole subject of card-room dust, and it is pleasing to note that one of the references was for inquiry and report on how the sickness rates for card-room operatives compare in stated respects with those of other workers in Lancashire spinning mills. This committee relegated the necessary statistical investigations to the Industrial Health Research Board, and the report of Dr. A. Bradford Hill, who conducted the inquiry, is now in print.[1] Though the publication has a rather comprehensive title, the subject-matter has not gone beyond the terms of reference, and we must congratulate the investigator on having made the best possible use of the somewhat limited material at his disposal. He had chosen the difficult task of searching the records of the several trade approved societies, and although he got a little help from the spinners and the winders, it would appear that he had to depend on the Card and Blowing Room Society for the effectiveness of his figures. This organization was at special pains to ascertain from each member his or her age and exact occupation, thus making possible the formation of age groups, the separation of card-room operatives from ring spinners and others, and the conversion of the latter into a control group. The sickness incidence for male workers in blowing-rooms and card-rooms respectively was compared with that of warehousemen, cop packers, and ring-room workers. It was shown that strippers and grinders and other male card-room hands had slightly less general sickness in the first five-year age group, but that after age 30 the rate steadily rose until it reached an excess of 83 per cent. at ages 50 to 59. Blowing-room men showed a similar increase after age 30. Respiratory diseases—bronchitis, bronchial catarrh, asthma, emphysema, congestion of the lungs, and pneumonia—likewise showed no striking differences in incidence up to age 30, but from ages 30 to 59 their prevalence among card-room workers was three times that of the control group, the blowing-room figures again being somewhat similar. Both single and married female operatives had up to age 50 rather less incapacity from all causes than ring spinners, winders, and reelers, but single women over 25 had an excess of respiratory sickness of 60 to 75 per cent. over the controls, and married women a similar excess after age 40. As ring-room spinners work in a hot and humid atmosphere, and are liable to develop respiratory diseases following on catarrhal colds, we suggest that these factors may partially account for the narrowing of the differences when compared with the males. It is stated for both men and women that the excessive loss of time was not due to lengthy illnesses, but to the very large number of short absences from work.

[1] Medical Research Council. Industrial Health Research Board. Sickness amongst Operatives in Lancashire Cotton Spinning Mills (with Special Reference to the Card-room). By A. Bradford Hill, D.Sc., Ph.D. Report No. 59. H.M. Stationery Office. 1930. (1s. 6d. net.)

Dr. Hill expresses a final opinion that localized exhaust and vacuum stripping have materially improved conditions in card-rooms, and suggests that, as the excess of respiratory diseases affects older workers only, the reason may be attributed either to the dusty conditions of other days or to the necessity of long exposure under modern conditions to produce deleterious effects. As the improvements mentioned were only introduced after 1912 he thinks that another ten to twelve years must elapse before this point can be definitely settled. The former theory, of course, presupposes that the improvements up to date have been universally adopted, and have fully met all requirements, but unless the report to be issued by the Departmental Committee shows this to be the case any such explanation can scarcely hold good. We understand that carding engines, apart from the stripping process, are continuously giving off quantities of fine dust, and that tenters are not only in close contact with this, but spend a big part of their time in brushing into the air the dust which has settled on the covers; also, if we add to these workers the tenters at drawing frames, lap machines, and combers, who are all promotions from card tenting, there still appear to be a fair number who have had several years' close contact with dusty cards under modern conditions. We are also informed there is still considerable hand-breaking and mixing of cotton, that the method of dust removal from under the cards of scutchers is not perfect, that vacuum cleaning of the machines is little practised, and that traversing vacuum strippers are only now replacing the older exhaust covers for brushes. An attempt was made to ascertain if the type of respirators introduced by Dearden in 1924 reduced the respiratory sickness incidence among 1,100 strippers known to have been wearing these for two years, but the difference shown between the year of wearing and the previous year was not sufficiently marked to justify any conclusion on this point.

ETIOLOGY OF THE COMMON COLD

So many allegations have been vainly made in the past as regards the origin of the common cold that the more recent attempts to fix the blame on the filterable viruses will be regarded for the most part with scepticism, tinged however with hope. Such organisms as the *Micrococcus catarrhalis, B. friedländer, B. septus,* Pfeiffer's bacillus, and the pneumococcus have at times seemed to be so predominant in the nasopharyngeal flora during catarrhal conditions as to arouse strong suspicion of their pathogenicity, and vaccine treatment has proved undoubtedly efficacious in some cases, though not in others. The systematic investigation which has been pursued for some years in New York by G. S. Shibley, A. R. Dochez, and Katherine C. Mills has led them, however, to the firm belief that the contagious cold in human beings is caused by "an invisible, uncultivable filterable agent, which in all likelihood belongs to the group of so-called submicroscopic viruses." In the *Journal of the American Medical Association* for November 22nd, 1930, these investigators recount their experiments, and indicate the way in which their conclusion was eventually reached. Colds were successfully transmitted from man to the chimpanzee (an animal with a nasopharyngeal flora closely resembling the human types), and from man to man, by the inoculation of Berkefeld filtrates of nasal washings obtained from persons suffering from spontaneous colds. The experiments were controlled as strictly as possible, but the results were obtained during a period of rising infection in the general community. The colds thus caused resembled in all respects those spontaneously contracted in the natural environment. One of the most significant sequels of introducing such filterable agents into the nostrils of the chimpanzee was the stirring up into greatly increased activity of such organisms as pneumococci, Pfeiffer's bacillus, and *Streptococcus haemolyticus,* which led to graver complications and influenza. This "stimulating" tendency of the filterable virus is regarded by these investigators as a phenomenon worthy of the most serious attention; it is to be hoped that confirmation or otherwise of their findings will be available before long. That this is the only way of producing colds in man may be doubted, but it is noteworthy that P. H. Long and J. A. Doull reported in the October issue of the *Proceedings* of the Society of Experimental Biology and Medicine that they had similarly transmitted colds to human subjects, and at a time of low general incidence, by the use of filtrates from which all bacteria had been excluded. In all cases it appears that the nasopharyngeal washings employed must be obtained within the first twenty-four or forty-eight hours of the onset of the infection. It may be, therefore, that the exciting cause of the common cold is different from that which is responsible for the continuation of the symptoms. This possibility would be in agreement with the suggestion of earlier observers that the aerobic organisms, incriminated previously, are secondary invaders, and have no etiological importance.

THE JAMES MACKENZIE INSTITUTE

Sir James Mackenzie has left his monument, more lasting than brass, "steadfast against the desperate north winds and the devouring rains" of the Old Grey City. There it stands, useful and unique, carrying on the traditions built up by the "Beloved Physician." In the eleventh annual report, just issued, a review of the year's work shows that the Institute for Clinical Research at St. Andrews is steadily adding to its laurels. It is well known that Mackenzie's later work was devoted to the study of disease in the stage before any structural changes were evident in the organs of the body. One of the main principles of the Institute is to deal with early symptoms and minor maladies, so that their mechanism of production and their bearing upon the future health of the patient may be determined. At the same time contact is maintained with the patients at their homes, and endeavours are made to discover the relation between environment, ailments, and subsequent disease. There is a special branch which concerns itself with the health of the child, and departments for bacteriology, chemistry, radiology, etc. A staff of local consultants is available if necessary. Mackenzie's teaching to general practitioners was, however, to carry on investigations themselves, so that the report is the result of work peculiarly within their province. One hundred and one new cases, and 1,140 additional notes were added to the files during the year, but probably the most interesting statistical data are those in the analysis of the records of the Institute. At the end of 1929 it was found that 62 per cent. of

the records were complete, 18 per cent. were incomplete, and 20 per cent. of the patients had been lost trace of. A special committee has reviewed 408 records during the year, and a considerable extension of the existing symptom index has been made. This will undoubtedly prove of great value to the future work of the Institute. Individual members of the staff undertook various researches during the year, these including work on the state of the tonsils and its relation to disease, the cytology of the blood in health and in common ailments, the etiology of the common cold and its relation to influenza, and a radiological investigation into the normal position of the abdominal viscera. In the children's department, which undertakes a most complete supervision of the health of the child, including his ante-natal history, an important addition has recently been made in that the school medical officer supplies the Institute with the notes of his periodic inspections. Already 252 cases are on the files with complete histories from birth to 5 years of age, and this is obviously most valuable material for the detailed study which is now in progress. Other activities of the Institute include public health research, and a wider area than formerly now benefits from its facilities; the laboratories have been as busy as in previous years, and thirty-nine weekly case-reading meetings of the staff have been held, in which all the difficult cases and problems demanding co-ordinate discussion have been dealt with. During the year the council decided to organize biennially a lecture on the application of the teachings of Mackenzie to general practice. The first lecture was delivered at St. Andrews by Professor John Hay of the University of Liverpool, and was fully reported in our issue of June 7th, 1930.

THE PRESCRIPTION OF LITERATURE

Dr. Gerald B. Webb of Colorado Springs spoke at the last annual dinner of the Association of American Physicians on "The prescription of literature," and this pleasantly phrased address, now published in the *Transactions*,[1] relieves the strictly professional interest of the symposiums on coronary thrombosis and on malignant disease of lung contained in the same volume. As he points out, there are many occasions on which it is much wiser "to prescribe, not a posset or a purgative, but an essay or a poem." Nor need he apologize for this as a new and revolutionary doctrine, for Rabelais, besides being an early demonstrator of anatomy and the inventor of the glottotome to cut the tongue-tie of an inarticulate woman, was (he believes) the first to prescribe literature to his patients, and, according to Coriat, wrote the romances of Gargantua and Pantagruel for the edification of those under his professional care. The medical man must be as familiar with his literary as with his Galenical remedies, for it would be a *faux pas* to recommend the *Life and Letters of G. H. Romanes*, who may have had a cerebral tumour, to a patient with that affliction, or to press Mrs. Gaskell's *Life of Charlotte Brontë* on those with pulmonary tuberculosis. Poetry may be read by only a few in this age of prose, but this is not an argument germane to its being read by the sick, for they are temporarily out of the hurry and scurry of ordinary modern life. Although no anthology is perhaps wholly acceptable to anyone except its compiler, anthologies are probably the best means of initiating the novice into verse, for they provide variety, an important element in successful treatment—the mind, like the body, thriving best on a mixed diet. With regard to prose works Dr. Webb recommends an example whereby monotony can be avoided: if Emerson is followed by Melville, and then Melville by Edgar Allan Poe, the probability is that none of them will pall. With many apt quotations much wise advice is gently given by one who has read widely and wisely.

"SAFETY WEEK"

The first "Safety Week" was held last year. Activities were carried out in places where branches of the National Safety First Association exist, and in a number of other districts, where local authorities took up the matter. The underlying idea was to arouse public opinion as to the necessity of additional effort to reduce the heavy loss of life from accidents of all kinds. The general experience in these districts was a marked reduction in the number of accidents on the streets and in industrial undertakings. In view of the success of this first effort, it is hoped to make the activities more widespread this year; several Government departments and a large number of unofficial societies are collaborating in a combined programme, which will be carried out from May 11th to 16th. Statistics speak for themselves. During 1929 approximately 18,000 persons were killed in accidents of all kinds, 7,000 being victims of street accidents; over 1,500 of the killed were children. On February 12th H.R.H. the Duke of York, as patron of this movement, will address a conference of local authorities in the Council Chamber of the Guildhall, with the Lord Mayor in the chair. The British Medical Association is represented on the National Safety Week council by Mr. E. B. Turner.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been printed; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who wishes to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

The Hughlings Jackson Lecture before the Section of Neurology of the Royal Society of Medicine will be delivered by Sir Charles Sherrington, O.M., F.R.S., on Thursday, January 29th, at 5.30 p.m.; the subject is "Quantitative management of contraction for 'lowest-level' co-ordination."

On the afternoon of Wednesday, January 21st, in the Great Hall of St. Bartholomew's Hospital, Lord Moynihan, P.R.C.S., presented to Sir D'Arcy Power, K.B.E., F.R.C.S., on behalf of the subscribers, the volume of Sir D'Arcy's *Selected Writings* which has been prepared in commemoration of his seventy-fifth birthday.

THE PEKING MAN

PROFESSOR ELLIOT SMITH'S INVESTIGATIONS IN CHINA

Before a large audience at University College, London, on January 15th, with the Chinese Minister in the chair, Professor G. Elliot Smith gave an account of his recent visit to Peking as the guest of the Chinese Geological Survey. His purpose had been to study the fossil remains of four representatives of the genus *Sinanthropus* and to visit the site at Chou Kou Tien, where excavation is still in progress. The Chinese Minister expressed the sincere thanks of the Chinese nation to University College for granting Professor Elliot Smith leave to enable him to visit Peking.

After paying a high tribute to the excellence of the laboratory work in Peking, and to the courtesy and hospitality of the Chinese authorities, Professor Elliot Smith said that the brain case found in the limestone cave at Chou Kou Tien in December, 1929, by Mr. W. C. Pei, a young Chinese geologist, was the most significant and illuminating relic of primitive man yet discovered. Its characters established a bond of union between the other two types of primitive man comparable in age, the *Pithecanthropus* of Java, and the *Eoanthropus* of Piltdown, which had previously seemed to be irreconcilable; indeed, both had been regarded with some doubt, and treated as suspect by certain anthropologists. The investigation in China had established a fuller measure of confidence in these other genera, and had destroyed any just ground for doubts regarding their character and significance. It had also given coherence to the information available about the earliest known members of the human family. The evidence of the geological age of the Peking man, the early Pleistocene epoch, was more certain than that of either the Ape man of Java or the Dawn man of Piltdown, for the remains were found on the spot where their original owners left them when they died in the cave at Chou Kou Tien, and the vast collection of animal bones, which had been studied by many competent palaeontologists, certainly belonged to creatures contemporaneous with the brain case. It was not possible to translate these geological data into figures of years, but Professor A. W. Grabau of the National University of Peking had claimed that the changes in the radioactive elements in early Pleistocene rocks—studied in the way first suggested by Professor Joly of Dublin—suggested an age of approximately one million years. This, however, was to be regarded at present as mere conjecture, and as providing only a general idea of the remoteness in time of these remains. Whether or not the Peking man was older than the fossils of Java and Sussex, he represented a more primitive type revealing generalized characters, some of them distinctly reminiscent of man's simian ancestry, and others strangely foreshadowing the qualities hitherto regarded as distinctive of *Homo sapiens*.

To justify the far-reaching claims for the exceptional importance of the discoveries in China, the lecturer devoted some time to the exhibition and description of photographs of the brain case discovered in December, 1929, and the second one, believed to be that of a young female, found later. The history of the search itself was as romantic as the actual discovery which rewarded the team of workers. Unlike other discoveries of remains of extinct types, when individuals accidentally found fossils and realized their importance, the Chinese discoveries were the result of years of persistent searching by a team of geologists and anthropologists, who had the insight to recognize clues and search for confirmatory evidence. When Dr. Zdansky found human teeth in a deposit containing Chinese fossils from this cave, he did not attach special significance to them, but Dr. Davidson Black of the Peking Union Medical College regarded them not only as a discovery of unique importance, but also as confirming the hope that had induced him to settle in Peking years previously. Dr. Black's conviction that epoch-making material awaited discovery at Chou Kou Tien was responsible for the intensive search which led to the great discovery. The lecturer included in his praise Mr. Roger Greene, the present executive head of the Peking Union Medical College, and Dr. Wong, director of the Geological Survey.

Particular attention was drawn to the thickness of the brain case pictured on the screen, and the lecturer said that it was not at present clear why there should have been this extraordinary thickness in comparison with the skulls of modern men. He also drew attention to the remarkable fact that, in spite of the closest search, it had been impossible to find any stone implements in or near the cave; it would appear that the implements used by these primitive men must have been of wood or some other perishable material. It was hoped that the exceptional thoroughness with which the full evidence had been supplied to anthropologists would prevent the development of such misunderstandings as had marred discussions over the fossil remains of man in the past; but in spite of all precautions, eminent palaeontologists in Germany, and also in France, were already claiming that the Peking man belonged to the genus *Pithecanthropus*, others in America that he was a Far Eastern example of Neanderthal man, and others, again, that the Chinese fossils were not human. Having himself recently made a careful examination of the actual remains in Peking, and compared them with human and simian skulls, Professor Elliot Smith could confidently support the claim of Dr. Davidson Black that *Sinanthropus* was a member of the human family who revealed in every quality of his skull evidence to distinguish him from all other known human types, and to justify the separate generic rank suggested to define his status.

NEW MOTOR REGULATIONS

In accordance with powers given by the new Road Traffic Act, the Minister of Transport has issued a comprehensive set of Regulations on matters concerning the construction of motor vehicles and their use on the highway. These are in addition to the specific requirements of the Act itself, and have been made after consultation with the Automobile Association and other interested organizations. The A.A. Legal Department has prepared a note on points of general interest to the motorist, from which we extract the following passages.

A motor vehicle must not be allowed to travel backwards for a greater distance or time than requisite for the safety or reasonable convenience of the occupants or other traffic on the road.

Every motor vehicle shall be so constructed that the driver, while controlling the vehicle, has a full view of the road and the traffic ahead. The person driving must be in such a position that he has full control over the vehicle and can retain a full view ahead. From January 1st, 1932, every motor vehicle other than a motor cycle must be fitted with a reflecting mirror.

All glass fitted to windscreens or windows facing to the front on the outside of any motor vehicle, except glass fitted to the upper deck of a double-decked vehicle, must be safety glass. All vehicles registered before 1932 are exempt until January 1st, 1937, but meanwhile the glass so fitted (safety or otherwise) must be maintained in a condition which does not obscure the driver's vision. "Safety glass" is defined as glass which, if fractured, does not fly into fragments capable of causing severe cuts.

Every motor vehicle must be constructed so that no avoidable smoke or visible vapour is emitted therefrom. The owner must maintain the vehicle in such a condition that it would not emit smoke, visible vapour, sparks, etc., which could be prevented by taking reasonable steps, or the exercise of reasonable care.

When a motor vehicle is stationary, otherwise than in enforced stoppages in traffic, the driver shall stop the action of machinery so far as may be necessary for the prevention of noise. Whenever necessary, the driver must give audible and sufficient warning of the approach or position of the vehicle. When the vehicle is stationary the horn must not be used, except when such use is necessary on the grounds

of public safety. The vehicle must not be allowed to stand on the road so as to cause unnecessary obstruction. The driver must not quit the vehicle without having stopped the engine and applied his brake.

Unless adequate protection is afforded by the body, the motor vehicle must be fitted with wings or other similar means to catch mud or water thrown up by the wheels. All brakes prescribed by the Regulations (the requirements vary with the type of vehicle) must be maintained in good and efficient working order and shall be properly adjusted. Every motor vehicle propelled by an internal combustion engine must be fitted with a suitable silencer or other contrivance for reducing the noise caused by the exhaust. Vehicles must not cause excessive noise (except from some temporary or accidental cause) through any defects or lack of repair, or faulty adjustment in the motor vehicle or trailer, or the faulty packing or adjustment of the load. They must be constructed and maintained so that no danger is likely to be caused to other road users. This applies equally to the weight distribution, packing, and adjustment of loads.

METHYLATED SPIRITS REGULATIONS

EXPLANATORY MEMORANDUM

In a leading article in the *Journal* of December 6th last (p. 968), we referred to the Methylated Spirits Regulations, 1930. The Commissioners of Customs and Excise have published an explanatory notice on the new Regulations (Notice No. 55) for the benefit of doctors, dentists, veterinary surgeons, hospitals, and nursing homes. This memorandum explains the new position so clearly that we reproduce it below, substantially in full.

Notice by the Commissioners of Customs and Excise

1. Any medical practitioner, dentist, veterinary surgeon, hospital, or nursing home may, on application to the nearest officer of Customs and Excise, obtain authority to receive industrial methylated spirits.

2. Industrial methylated spirits consist of 95 parts of ethyl alcohol denatured with 5 parts of wood naphtha. They may be obtained in various strengths, including a strength corresponding to that of absolute alcohol.

3. Industrial methylated spirits received under an authority as in paragraph 1 may be obtained either from a methylator (in quantities not less than five gallons at one time) or from any wholesale chemist or dispensing chemist authorized to sell them (in quantities not exceeding four gallons at one time). On each occasion a "requisition" (in an official form, a book of which will be supplied by the officer of Customs and Excise) must be forwarded to the supplier.

4. Without obtaining any authority, any medical practitioner, dentist, veterinary surgeon, hospital, or nursing home may obtain industrial methylated spirits in quantities not exceeding half a gallon at one time, from any wholesale chemist or dispensing chemist authorized to sell them, merely on a written order signed by a medical practitioner, dentist, or veterinary surgeon. Hospitals and nursing homes should arrange for a doctor to whom they are known to sign orders for them.

5. Industrial methylated spirits received under either paragraph 1 or paragraph 4 may be (*a*) used in making up articles to be dispensed for medical, surgical, dental, or veterinary purposes, or (*b*) used or dispensed without admixture, or diluted with water, for any medical, surgical, dental, veterinary, or scientific purposes, but may not be used or disposed of for any other purposes.

6. In all cases the following conditions must be observed:

(i) To every bottle or other container dispensed to a patient and containing either an article made with industrial methylated spirits or industrial methylated spirits must be affixed a label bearing the words "For external use only," "Not to be taken," or otherwise to the same effect.

(ii) No greater quantity than one pint of industrial methylated spirits, either alone or as an ingredient in any article, may be dispensed at one time to or for the use of any one person.

Scotland

Professor Muir's Portrait

On the afternoon of Tuesday, January 20th, in the Randolph Hall of the University of Glasgow, Sir Frederick Gowland Hopkins, President of the Royal Society, presented to Professor Robert Muir, M.D., F.R.S., on behalf of the subscribers, his portrait in oils by G. Fiddes Watt, R.S.A., and to the University a bust by G. H. Paulin, A.R.S.A. Professor Muir has held the Chair of Pathology in the University since 1899.

St. Mungo (Notman) Chair of Pathology, University of Glasgow

The curators, at their meeting on January 7th, appointed John Shaw Dunn, M.A., M.D., to the St. Mungo (Notman) chair of pathology in the University of Glasgow, in succession to the late Professor John Hammond Teacher. The holder of this chair is *ex officio* pathologist to the Royal Infirmary, where he has, in the pathological institute, accommodation and facilities for teaching and research. Professor Shaw Dunn is 47 years of age, and was educated in Glasgow. After graduating M.A. in 1901, and M.B. with honours in 1905, he took the degree of M.D. with honours in 1912, gaining a Bellahouston gold medal for excellence in this thesis. He then held resident posts in the Royal and Western Infirmaries and in the Royal Hospital for Sick Children. Thereafter he became assistant in the pathological department of the Western Infirmary under Professor Muir, holding appointments in turn as lecturer in pathological histology and in clinical pathology in the university and director of the clinical laboratory in the Western Infirmary. During the war he was attached to the R.A.M.C., from which he retired with the brevet rank of major, and published important papers on war nephritis and gas gangrene. In 1919 he was appointed professor of pathology in the University of Birmingham, and in 1922 became Proctor professor of pathology in the University of Manchester. He has made numerous contributions to pathological literature in addition to those already mentioned.

Care of the Child in Scotland

Under the auspices of the Edinburgh and Leith Parents' and Parent-Teachers' Associations, a lecture was delivered on January 14th by Dr. John Guy, medical officer of health for the city of Edinburgh, who said that the past year had shown, with the exception of two war years, the lowest birth rate yet recorded in Edinburgh. During his own lifetime the fall in the birth rate in the city had been exactly 50 per cent. Approximately 7,500 children had been born in 1930. In his opinion the excuse for the low birth rate, often advanced at the present time, that quality was better than quantity, was untenable. The fact that the number of children born diminished each year so that families became smaller and smaller might be a condemnation of present modes of living. The Scottish race had been, and was, of too good a quality to be allowed to die out without regret, for a persistently declining birth rate ultimately meant the passing away of a race. Last year the birth rate was 17 per 1,000, and the death rate approximately 14, so that there were only 3 persons to the good out of every 1,000 living. A family of four might be regarded as a reasonable minimum. He had found that of the 7,500 children born, 250 died before they were 4 weeks old, and he wondered how many of these children would have lived if they had been borne by well-developed, healthy mothers. In regard to the care of young children, he thought that, while physical and mental training was important, it was

also necessary to develop the moral side of a child's life. Although this was accomplished partly in school life, parental influence had probably the most permanent effect.

New Falkirk Infirmary

The Right Honourable William Adamson, Secretary of State for Scotland, addressed a public meeting at Falkirk on January 9th in connexion with the opening of the new Falkirk Infirmary, which has just been completed at a cost of approximately £100,000. Dr. John Young, chairman of the Board of Managers, presided, and said that in the past Falkirk Infirmary had been one of the few institutions in Scotland whose expenditure had not exceeded its income. In supporting a resolution to increase the contributions from workmen and other subscribers to the infirmary, Mr. Adamson remarked that it was hardly necessary for him to preach to the Falkirk people on this subject. They had already built an institution which would need monetary support for its maintenance. The evolution of workmen's contributions to social services, including the infirmaries, demonstrated that the working classes were whole-heartedly behind this service, and that they would see it through. Although he was not prepared to detail facts and figures, he wished to say that certain sections of workmen had reconsidered the question of weekly contributions. They had not only to support district infirmaries and hospitals, but they were called upon to subscribe to central institutions, such as the Royal Infirmary of Edinburgh. In general, such working-class contributions would have to be raised from a penny to twopence a week. Mr. Adamson said that he had lived among working men practically all his life, and he had never met a workman who complained of his contribution to the local or district infirmary as a burden. He emphasized that these infirmaries had always been maintained by voluntary effort, and that what had already been done could be repeated. The people of Scotland had to realize their responsibility by adequately supporting all such institutions.

Ireland

Public Health in the Irish Free State

The fourth report of the Department of Local Government and Public Health in the Irish Free State, which has been recently published, covers the twelve months ending March 31st, 1929, and comprises sections on local finance and general administration, public health, housing, public assistance, and roads. During the period reviewed there was a fall in the general mortality rate to 15 per 1,000, pulmonary tuberculosis and influenza being markedly less fatal; there was, however, an increased death rate for measles and diarrhoeal diseases. Boards of health are now required to furnish monthly classified summaries of cases of enteric, typhus, puerperal and scarlet fevers, and diphtheria which are admitted to local fever hospitals. The county medical officers of health each week also forward to the central department comprehensive detailed returns of notified cases of infectious disease. In the twelve months there were reported 29 cases of typhus fever, 304 of enteric, 989 of diphtheria, and 1,148 of scarlet fever. Typhus fever was recorded in the rural districts of Clare, Donegal, Galway, and Kerry, but no outbreak was extensive. In Kerry, which has suffered severely from this disease in past years, portions of the county having even been classifiable as endemic areas, a systematic campaign has been organized against it, including the disinfecting and delousing of infected households in each area successively. A scheme for the eradication of diphtheria was undertaken in Louth, where children between the ages of 6 months and 6 years were submitted to the Schick procedure. Diphtheria immunization schemes are being brought into operation also in Dublin and Cork. An attempt is being made to establish county schemes of pathological investigations at central laboratories, which will also arrange for the bacteriological analysis of milk and of water. The complaint is again recorded that lack of uniformity in the public health administration throughout the Free State continues to menace the health of the community and to limit the improvement of external trading.

The medical inspection of school children is steadily extending, but much remains to be done as regards the subsequent treatment. There has so far been revealed a high incidence of carious teeth, enlarged tonsils and adenoids, and defective vision, but all tuberculous deformities and other forms of crippling were fewer than had been anticipated. Emphasis is laid in the report on the need for tracing more completely the occurrence of septic foci which may give rise to rheumatic manifestations, and for detecting as early as possible defects of the eyes and ears. Follow-up measures are conducted by district nursing associations, of which there are now 124 affiliated with the Queen's Institute of District Nursing. More attention should be paid to the condition and equipping of schools. Improvements have been made in the organized campaign against tuberculosis; there are twenty-one central tuberculosis dispensaries, and 154 branch ones. The improvement in the tuberculosis death rate is attributed to a decline in the incidence of the pulmonary form; the decline in non-pulmonary cases, though less marked, is considered promising. Standard schemes for dealing with the blind have been established in three county boroughs and twenty-one counties, while partial benefits were available in two other counties. Two county boroughs and nine counties have now adopted approved arrangements for the diagnosis and treatment of venereal disease.

Health of Belfast in 1929

The annual report on the health of the county borough of Belfast for 1929, prepared by Dr. C. S. Thomson, medical superintendent officer of health, is for the first time drawn up in the form prescribed by the Ministry of Health in England, and represents the foundation upon which future reports will be based. Dr. Thomson comments on the fact that Belfast has no serious slum problem, or any real housing question apart from the necessity of paying attention to buildings which are growing old. As regards house accommodation there has been a slightly retrograde movement since 1911, but, even so, 92 per cent. of the inhabited private houses were occupied by single families. Among nearly 90,000 families in Belfast there were only about 7,000 who shared a house; over 40 per cent. of the families occupied four rooms each. A survey was made with a view to assess overcrowding, and it was found that the overwhelming majority of people living in houses or rooms which were overcrowded, according to the standard of the English Registrar-General, were in employment. The rents in a very large majority of cases were remarkably low, but the wages were often poor, though by no means always so. The deduction is drawn that if the Corporation sets out to build houses for the overcrowded section of the population money will be lost. Evidence was obtained supporting the conclusion that the incidence of tuberculosis is related to housing. Dr. Thomson urges the adoption of further educational measures with a view to instructing the citizens of Belfast in the application of the laws of health; the holding of a "health week" in alternate years is contemplated, and more use will be made of cinematograph films and other forms of

propaganda. Six centres for maternity and child welfare were operating in the year under review, but there are no municipal ante-natal centres, though three hospital ante-natal centres exist. The conclusion is reached that a definite scheme is required for maternity and child welfare comprising the services of a whole-time medical officer and nine additional health visitors. During the year no complaint was received of contamination of the city water, the quality and quantity of which are reported as excellent. In his capacity as port medical officer, Dr. Thomson gives details of the arrangements made for preventing the introduction of infectious diseases. No cases of plague, cholera, yellow fever, smallpox, or typhus occurred, and no plague-infected rats were discovered during 1929.

Dr. Andrew Trimble, chief tuberculosis officer to the Corporation, submits a report on the work of the tuberculosis department, in which he calls attention to the useful reorganization which has been achieved, effecting closer co-operation in public health work generally. During the year 1,805 persons notified as suffering from tuberculosis were examined, as compared with 1,816 in the previous year. Of the 1,805, 54 per cent. were found to be tuberculous, and 6 per cent. doubtful. Dr. Trimble gives a table illustrating the declining trend of the death rate from pulmonary tuberculosis during the last twelve years, and shows that for every 100 who died from the disease in Belfast in 1918, only 42 died in 1929, a reduction of 58 per cent. in the rate. He emphasizes the importance of providing more open-air schools for delicate children, more intensive education of the people with regard to the prevention of the disease, the addition to the medical curriculum of a course in tuberculosis, and the extension of accommodation for children suffering from non-pulmonary forms.

Armagh Union Infirmary

While expressing satisfaction with the improvements carried out to the buildings of the Armagh Union Infirmary and Fever Hospital since the last report was received, the Minister of Home Affairs has directed the attention of the board of guardians to the serious overcrowding of male mental patients, and to the fact that only one ambulance has been available for transporting patients with infectious and non-infectious diseases. Other matters mentioned included defective arrangements for drying clothes, the unsatisfactory system of conveying food to the infirmary, and lack of a disinfecting apparatus. The report has been referred to a committee.

England and Wales

Silicosis and Coal Mining

At the annual meeting of the Institution of Mining Engineers, held in London on January 15th, Dr. J. S. Haldane introduced the subject of silicosis in coal mining. Silicosis, he said, was a disease of the lungs brought about by the inhalation of siliceous dust, and leading to tuberculous infection. Hence deaths from silicosis, when they occurred, were nearly all returned as due to tuberculous lung disease. There was, however, also clear evidence that inhalation of siliceous dust led, or might lead, to deaths returned as due to bronchitis, so that deaths from bronchitis had also to be taken into account in connexion with silicosis risks. After quoting the statistics of the Registrar-General showing deaths from phthisis and from bronchitis among coal miners and other workers, especially workers in stone, Dr. Haldane said that neither the statistics nor any other evidence whatsoever showed that any class of work in coal mining was subject to risk from silicosis except under very unusual conditions which could be guarded against effectively. Nor was there any clear evidence that dust inhalation by coal miners was an ordinary cause of either bronchitis or pneumonia among them, though it seemed practically certain that excessive inhalation of coal dust or shale dust must cause bronchitis and ought therefore to be avoided. While the evidence did not reveal the existence of any silicosis among coal miners, other direct evidence had shown in recent years that in exceptional circumstances very great risk might occur among men driving roads through sandstone or other siliceous rock. The precautions required in work in sandstone or similar rock were quite simple. To prevent inhalation of dust from machine drills an effective form of the dust-trap worked out by Captain Hay of the Mines Department should be used, along with good ventilation; to prevent harm from the dust produced by blasting, no one should return until the place had been thoroughly cleared by ventilation; and to prevent harm from dust raised in shifting the broken rock, it should be thoroughly wetted. Dr. Haldane added that the fact that coal miners were, and had been for generations, less subject to phthisis than average persons was very striking, considering their conditions above ground. The coal dust and shale dust which they breathed were not antiseptic substances, but it must be supposed that some soluble constituent in this dust stimulated the phagocytes to activity, so that they digested and destroyed the bacteria in the lung alveoli. This would account for the relative immunity to phthisis of a coal miner or coal boat loader. On the other hand, when certain kinds of dust containing free silica were breathed, the defence against tuberculous infection broke down, and the disease familiarly known as miners', grinders', potters', stone-masons', or other occupational phthisis became prevalent, commonly accompanied, though not always, by a marked increase in bronchitis mortality. Dr. Haldane could not agree with the view put forward lately at a congress in Johannesburg that the risk of silicosis was simply proportional to the ratio of free silica in the dust. Touching finally on the question of compensation for silicosis in the coal-mining industry, Dr. Haldane said that the matter was rendered difficult by past neglect of the provisions of the Mines Act. There were a certain number of men suffering from undoubted silicosis—apparently dying—who could obtain no compensation under existing law, since the exposure from which the illness resulted was at a time before the law applied.

Post-Graduate Clinic at Hampstead

A post-graduate school has been established at the Hampstead General and North-West London Hospital. Meetings will be held there every Wednesday afternoon at 4 o'clock, when discussions of interest to general practitioners will be opened by members of the medical staff. Membership of the school is being confined to doctors practising in the North-West of London; there will be no subscription. The inaugural meeting will take place on Wednesday, January 28th, at 4 p.m., when an address on maternal mortality and morbidity is to be given by Mr. Comyns Berkeley. It is hoped that these post-graduate afternoon clinics will serve as a rallying ground for all practitioners within about five miles of the hospital, and help them to keep in touch with the latest advances in medicine. The dean of the school is Mr. Clifford Morson. Successful work along the same lines has been done at the Royal Northern Hospital for some years past.

Correspondence

VACCINATION AND ENCEPHALITIS

SIR,—In the leading article in your issue of January 17th, which deals with the second report of the Rolleston Committee, there are two points upon which, with your permission, I should like to offer a few comments, more especially as that committee (of which I had the honour to be a member) is now dissolved.

The first point is as follows. In discussing the two rival hypotheses as to whether the encephalitis in question is brought about by vaccinia virus itself, or by another virus activated by vaccination, the following sentence occurs: "Neither side can claim much help from experimental infection of animals, since neither vaccinal nor any other form of encephalitis has been produced in animals inoculated from the nervous system of fatal cases." Now while it is true that direct inoculation of the central nervous system of fatal cases of post-vaccinal encephalitis into animals has given negative results, other animal experiments that have been carried out have given results that afford a possible explanation of these negative results. Thus, in the appendix to the first report of the Rolleston Committee, an account was given of some experiments carried out by me in which the effect was determined of introducing a particularly potent brand of calf lymph intracerebrally into rabbits. When the dose was strong enough twelve of these animals developed encephalitis, of which they died, and at post-mortem examination the opportunity was taken of determining the distribution of vaccinia virus in their central nervous system and elsewhere. No fewer than ten of these twelve animals succumbed from the sixth to the tenth day after inoculation, and in all of them the virus was abundant in the brain. On the contrary, in the case of the two other rabbits that survived till the twelfth and the thirteenth day, no vaccinia virus could be found in the brain. These results therefore indicate that after the tenth day the virus is no longer in evidence in the central nervous system, even when the encephalitis is produced directly by vaccinia virus. This process of "autosterilization," as Levaditi has called it, may conceivably have something to do with the negative results referred to.

The second point is in regard to the beneficial effect of convalescent serum, which was employed first of all by Sir Thomas Horder in the case admitted to St. Bartholomew's Hospital in May, 1929, and subsequently and independently by Hekman of Rotterdam in a number of cases with encouraging results. When Sir Thomas did me the honour of calling me in to consultation over the case referred to, I recommended that serum from the mother (who had been vaccinated the same day as the child) should be taken on the fourteenth day after vaccination and given to the child. The choice of the fourteenth day was the result of a considerable number of experiments previously carried out on rabbits for the specific purpose of determining the best time to collect serum for protective purposes. In each of three sets of experiments the animals' serum gave optimum protection on the fourteenth day after vaccination.

Although the problem of post-vaccinal encephalitis is still very far from solved, I venture to submit that animal experiments have not been without profit.—I am, etc.,

London, W.C.1, Jan. 19th. M. H. GORDON.

THE OUTLOOK ON TUBERCULOSIS

SIR,—The bold advocacy by Sir Robert Philip of the routine use of the tuberculin test "at stated intervals from early infancy onwards," which you have so strongly supported, will not fail to arouse widespread interest. With this advocacy those who recognize the practical implications of the procedure will be in warm agreement. But when the proposition is submitted to a cool, critical examination, with the view of ascertaining what precisely the practical implications are, we arrive at matters requiring elucidation. It may be taken that a scheme of this magnitude, which if energetically launched is capable of being rapidly brought into action, is no mere epidemiological study. The figures quoted by you—namely, 37.7 per cent. of children infected with tuberculosis at the age of 5 years, and 90.2 per cent. at the age of 18—are for the moment sufficiently informative. Let us suppose the fact and date of tuberculization to have been duly noted in relation to each child. What practical use is now to be made of the information?

Sir Robert Philip's answer to this question is: Concentrate upon the reactors with "watchfulness," "maintenance of high level of resistance," "effective detuberculization," "anticipative and preventive procedure." If we exclude, as Sir Robert Philip appears to do, specific methods of immunization, this answer is too nebulous to be of any more value for the reactors than for the rest of the population. Writing in 1923 in advocacy of the percutaneous use of a tuberculin ointment as being "of effective value in the direction of general detuberculization," Sir Robert Philip soundly observes: "If the validity of any method of *de*tuberculization be established, it is clear that the earlier in the life-history of the infected individual it is adopted, the speedier and completer will be the effect achieved" (*British Medical Journal*, March 24th, 1923, p. 495). But even the assistance of the percutaneous use of tuberculin ointment appears to have no place in the list of advantages to be derived from the routine use of the tuberculin test to-day. In announcing his conviction that "extended knowledge of the facts, and the application of anticipatory measures which will be consequently demanded, will lead to better results than attempts along the line of enforced vaccination," Sir Robert Philip goes on to state categorically: "Attempts at vaccination have been numerous. . . . One after another they have been proposed on scientific grounds. . . . *They have been tested and, so far, all have been found wanting.*" Although perhaps the language is somewhat ambiguous, the general impression left upon the reader's mind is that the preventive and anticipatory measures upon which he dwells do not include specific immunization.

With this view, if I have correctly gauged it, I am in profound disagreement. There is good reason to believe, with Koch and his successors, that curative and preventive immunization, in relation especially to such tuberculous infection as is now under consideration, is an accomplished fact. In spite of the failures of the past, there has been sufficient success to make it more than a hope—knowledge founded on evidence—that specific immunization, supported by ordinary hygienic measures, is capable of rounding off the argument in favour of a wide use of the tuberculin test by a definite, trustworthy promise of eradication of the infection thus to be detected.

I would respectfully submit that a demonstration of the truth of this statement is the next most important step in the campaign against tuberculosis.—I am, etc.,

London, S.W., Jan. 17th. ROBERT CARSWELL.

SIR,—It was with much pleasure that I read in the *Journal* Sir Robert Philip's address on the above subject. The present favourable position of the campaign against tuberculosis is due almost entirely to his genius, and courageous persistence in spite of much opposition.

Nobody who takes a comprehensive view of this most intriguing subject can fail to agree with his dictum, that, while much is done for those suffering from tuberculous disease, very little is done for those suffering from tuberculous infection—a much more hopeful subject from the

point of view of treatment. I am firmly of opinion that little further progress will be made until the significance of tuberculous infection is appreciated and seriously treated. In a previous article in the *Journal* I pointed out that tuberculous infection was relatively common among children of school age, while tuberculous disease was correspondingly rare, yet no preventive treatment is undertaken until the infection becomes a disease. While tuberculin must be regarded as the more precise index, it is not difficult for an experienced man, by clinical methods alone, to detect tuberculous infection. Public health departments, in the sphere of preventive medicine, are thinking too much in watertight compartments. There is much truth in the statement that the school medical officer, who is in the best position to detect tuberculous infection, rarely sees tuberculous disease, and the tuberculosis officer rarely sees tuberculous infection.

Again, the general practitioner, who should receive every encouragement to familiarize himself with the earliest signs of tuberculous infection, not merely tuberculous disease, is persistently kept in the background in this as in all other branches of preventive medicine. The child suffering from tuberculous infection is the potential consumptive of the future, and no man can foretell the ultimate course in any given case. It is only by early recognition and close observation of the infected child that prevention can be successfully practised. A new orientation is indeed urgently required, and no one is better fitted than Sir Robert Philip to give the necessary lead.—I am, etc.,

Birkenhead, Jan. 12th. D. J. GAIR JOHNSTON.

SIR,—I have read with the greatest interest, in the *Journal* of January 10th, Sir Robert Philip's lecture, and your leading article on the diagnosis of latent tuberculosis. I absolutely agree with him on the fundamental value of the various tuberculin tests. The intradermal test was described by Mantoux in 1908, and is extensively used in all children's hospitals on the Continent and in the United States, yet in this country its usage is quite exceptional, although, as Sir Robert points out, "the knowledge obtained by it is priceless." During and after the war, when there was an immense increase in tuberculosis in children in Vienna and Germany, the value of this test, also of the von Pirquet test, was established beyond all doubt. Now tuberculosis, as it occurs in the child, differs widely in its pathology from that of the adult, yet the subject of pulmonary tuberculosis is still taught in many of our leading medical schools by a specialist in adult tuberculosis, who is often quite unfamiliar with tuberculosis in the child. Examination of contact cases is largely left to the specialist in adult tuberculosis, and thus many paediatricians see very few cases of tuberculosis in children, with detriment to their teaching. Surely it would be better if the care and treatment of tuberculosis in childhood, and teaching in this subject, were left in the hands of the children's physician. At this point I would like to suggest that if possible a translation of Pirquet and St. Engel's great book on tuberculosis in childhood, published last year, should be made at once, so that all teachers in diseases of children, and tuberculosis experts, may acquaint themselves with this, the greatest book yet published on this subject.

There is one paragraph in Sir Robert Philip's lecture that compels criticism. "Vague conditions of 'delicacy' in the child may find their explanation—for example, malnutrition, obscure feverish attacks, ill-defined lack of energy, so-called 'disturbed action of the heart,' which may interfere with the claims of education and sport. Such conditions, I am satisfied, are very frequently the expression of tuberculous infection." If one takes a group of cases of "nervous debility" and "malnutrition" in children, and tests their Mantoux reactions, one does not find a higher percentage of positives than in a similar group of apparently normal children. To term such symptoms "tuberculosis" is surely going too far. For the mother the word "tuberculous" is practically synonymous with "consumptive," and many doctors faced with a case of this sort may recommend sanatorium treatment, where the chance of secondary tuberculous infection is increased. Undoubtedly tuberculosis carries with it too great a stigma to justify anyone in diagnosing it easily in such delicate children. Surely the value of the positive Mantoux test lies rather in stimulating the doctor to take extra precautions to get the child back to full health as rapidly as possible.

The fact of tuberculization is, as Sir Robert Philip says, extremely important, but, in my opinion, for another reason—namely, that the earlier the age at which a positive reaction is found, the more likely one is to find the adult that is disseminating the infection. It is mainly through the early detection of these adults that reduction in the incidence of tuberculosis in childhood will eventually occur. It should be regarded almost as a criminal offence to allow adults with open pulmonary tuberculosis to come into near contact with young and delicate children, yet to-day this is still a frequent occurrence. If tuberculosis in childhood is to diminish, it seems that the following conditions must be fulfilled:

1. Much greater facilities for the care and treatment and for teaching in tuberculosis in children should be given to children's physicians.

2. All who have had to do with tuberculosis in childhood should carefully criticize all articles and books written on the subject before the advent of *x* rays and tuberculin tests. It is hoped that all will read Pirquet and St. Engel's great book, which contains practically all our scientific knowledge up to date.

3. The value of tuberculin tests in childhood should be much more generally realized.

—I am, etc.,

St. Thomas's Hospital, Jan. 12th. JOHN GIBBENS.

TUBERCULIN AND THE TUBERCULOSIS PROBLEM

SIR,—The prominence given to tuberculin as a diagnostic agent in Sir Robert Philip's address and your leading article in the *Journal* of January 10th afford me unalloyed pleasure. We are within sight of a goal that is worthy of our aim. Forty years after its discovery English physicians may be persuaded to use the one indispensable agent for tracking tuberculosis to its source.

We have always been at a great disadvantage, because the true solution of the problem of tuberculosis needed, above everything, constant, intimate, and tedious observations upon the lesions disclosed after death. The wealth of such observations in other countries, notably in Germany, is the best measure of our own poverty. It was for this reason that I urged in the *Times* not long ago the creation of a Government institute, similar to Koch's institute in Berlin, for the study of tuberculosis on scientific lines. There can be no great progress till we are allowed to follow the disease to the bitter end. Let us be wise and change the orientation of our conceptions and methods, and deal with the problem in accordance with the logic of accepted facts that have been revealed to us by the labours of Koch, Römer, Ghon, Ranke, Redeker, and others, whose views have been based upon the bedrock facts of bacteriology, pathology, and epidemiology.

I do not think the writer of your leader would persist in his view that "pulmonary tuberculosis is spread as much by apparently healthy carriers as by patients suffering from the clinical disease" if he had studied Redeker's article in the *Zeitschrift für Tuberculose*, Bd. 43, Heft 6, "Die epidemiologie der ambulanten kindlichen tuberculoseformen." Beyond all doubt tuberculosis is a disease that begins in childhood, and the environment of the child is the source of infection. Too much attention cannot be paid to the environment of the child if we wish to tackle infection at its source. The sanatorium cannot prevent infection in childhood, and plays a very trifling part in converting infectious into non-infectious cases.

The problem of prevention is not touched by the existing system of sanatorium treatment for a few months, nor by the glorification of fresh air and sunshine. Neither fresh air nor sunshine can prevent tuberculosis in children living in the houses of consumptive parents. The key to the detection of the danger spots has not been used comprehensively, consistently, and courageously. The primary duty of State medicine should be to reduce the incidence of tuberculosis infection in young children. Next in importance to the testing of children with tuberculin comes the provision of homes for advanced and infectious forms of phthisis, supported by the Government. Even when the disease is far advanced, tuberculin as a remedy may sometimes work wonders; thus these homes would become hospitals for specific treatment, and, further, they would greatly prevent the incidence of serious infection with tubercle bacilli in children. But all these modifications of existing systems should be discussed by a special commission of experts, with a lawyer as chairman. Conflicting interests and views would be inevitable, and a lawyer would be able to sift the wheat from the chaff, and prejudices would be at a discount. Vested interests and reputations might suffer, but a deeper knowledge would find the clue to a solution of the problem of preventing tuberculosis in children.—I am, etc.,

London, W., Jan. 11th. W. CAMAC WILKINSON.

INCUBATION PERIOD OF MEASLES

SIR,—The records of incubation periods in measles given by Dr. Goodall in his letter in the *Journal* of January 10th show an interesting agreement with a distribution which we arrived at from notification records in St. Pancras, and which was first published in a table at the top of page 391 of "A study of the epidemiology of measles" in the *Annals of Eugenics* (vol. iii, 3-4, 1928).

This distribution was obtained by tabulating the intervals in days between the dates of appearance of the rash in pairs of cases of measles occurring in the same house during the years 1924-28, and the portion of this distribution from six to twenty days is reproduced below. There were 2,490 of these intervals, and in Dr. Goodall's data there were 115 intervals of from six to twenty days. Reducing the total of 2,490 to 115, the expected figures would be as shown in the third column, and these may be compared with Dr. Goodall's data in the fourth column.

Interval in Days	St. Pancras Notification Data		Dr. Goodall's data
	Actual Frequency of Intervals	Expected Frequency in a Total of 115	
6	90	4	1
7	99	5	5
8	173	8	7
9	236	10	9
10	318	15	17
11	353	16	18
12	329	15	16
13	269	12	6
14	205	9	8
15	153	7	10
16	104	5	7
17	70	3	1
18	48	2	2
19	38	2	4
20	35	2	4
Total ..	2,490	115	115

Applying the usual statistical test for "goodness of fit" between the distribution expected from the larger data and that actually found, by squaring each difference and dividing by the expected number and then summing the resulting figures, it appears that for the fifteen groups the total (which statisticians call *chi squared*) is 13.6, and by reference to statistical tables this is found to denote that as poor a correspondence would be found about once out of every two sets of such data through chance alone. In other words, the degree of correspondence is as good as might be expected on the theory of probability, in view of the size of the data.

This is of interest because it shows that (1) the employment of good notification records in the way I have advocated leads to results consistent with those obtained by more carefully controlled clinical observations in isolation hospitals, and (2) the interval between the appearance of the rash in successive cases in the same house provides, at any rate for statistical purposes, as good a measure of the incubation period as can be obtained by other methods.—I am, etc.,

Department of Applied Statistics, University College, London, Jan. 14th. PERCY STOCKS.

FAMILIAL INCIDENCE OF CANCER

SIR,—The recently published scientific report of the Imperial Cancer Research Fund is a document of the first importance. On page 139 may be found the words "There are references in the literature to so-called cancer families—but these are of doubtful validity." Truth may be learnt from fact, from reason, and from experience. General practitioners know from experience that cancer families exist, though they are usually denied the opportunity to prove the fact by demonstration at necropsy.

I am personally acquainted with a family where both parents died of cancer, and five of the six children who reached adult life have died of cancer. The remaining child survives. At a recent funeral the assembled relatives could not recollect any collateral (that is, cousins) who had passed middle life and who had died of any other cause than cancer. In a second family the mother was the thirteenth member to die of cancer; one of her four children died of cancer of the stomach, and his daughter had a breast removed for the same disease.

If the familial incidence of cancer is important, as I believe it is, would not the resources of the Fund be well spent in investigating families such as the foregoing? What standard of proof is required? That cancer should be the certified cause of death, with the word of a general practitioner that the clinical signs were typical, seems insufficient.—I am, etc.,

GRIFFITH EVANS, D.M., F.R.C.S.

Caernarvon, Jan. 18th.

TREATMENT OF ETHMOIDITIS

SIR,—In your issue of January 10th appears a paper entitled " A safe method of dealing with ethmoiditis," by my colleague Mr. Peters. I had the privilege of hearing him read it before the Section of Laryngology at Winnipeg, but owing to the plethora of other papers then presented, there was no time for discussion. It is not quite clear to me what the essential points are which he desires to emphasize, as constituting the safety of the method he advocates. Is it in the preliminary radiographic examination of all cases before operation for evidence or otherwise of any accessory sinus infection, or his method of operative approach, or the direct examination of the various sinuses during operation and their drainage if necessary, or all these combined? Personally, I use the combined method, as in my experience any case of long-standing ethmoiditis infects one or more, or all, of the adjoining sinuses, and this is particularly so where purulent changes supervene on the hyperplastic or polypoid type of ethmoidal disease, and, unless all the other infected sinuses are drained when dealing with the ethmoid, there is little hope of getting a good result.

I agree as to the need for the removal of the middle turbinal as essential to the proper approach to the ethmoidal cells, but instead of using a Luc's forceps, which was my former practice, I have for many years severed its attachment with a special nasal scissors, and then removed it with a nasal snare containing a rather stout wire. This gives as clean severance of its attachment as that procured by the Sluder knife in the preliminary incision advocated by him in his radical operation. The diseased ethmoidal cells are then removed, from before backwards to the sphenoid, by a round-ended Luc's forceps, or, if the cell walls are friable, a ring curette, drawn from above downwards, from the level of the middle turbinal stump to the upper border of the inferior turbinal, is a safe and efficient procedure. This leaves the sphenoidal sinus easily accessible for examination of its contents and drainage if necessary. The frontal infundibulum can be cleaned out with a reverse-action curette and rasps, and the antrum punctured, washed out, and, if infected, drained intranasally below the inferior turbinate. In my opinion, nothing short of this procedure is likely to give satisfactory results, and, when even all this is done, in a few cases an infected aberrant ethmoidal cell may remain beyond the reach of safe surgical approach, to partly mar the surgeon's hope of a complete cure.—I am, etc.,

London, W.1, Jan. 12th. JOHN F. O'MALLEY, F.R.C.S.

THE " DEEP POOL " BATH

SIR,—I have read with great interest the very instructive and original article on a method of exciting movements in weakened and paralysed muscles, in your issue of January 10th, by Mr. Arthur Porritt and Mrs. Guthrie Smith. Their aim is to give in their cases exercises and movements based on the idea of primary relaxation, and of producing a maximal movement with a minimal muscle effort by the removal of extraneous forces—in particular, gravity, the weight of the limb, and friction—which leads to the abolition of fear and its concomitant involuntary spasm, and to the growth of confidence, and consequent ability to assist voluntarily in the restoration process. The apparatus by means of which they attain this ideal is admittedly simple, and, as I know from personal observation at St. Mary's Hospital, where they use it, effective. I feel, however, that it is only just to that much-suspected handmaiden of therapeutics—hydrology—to point out that all these effects can be, and are, attained by the immersion of the limb, and where possible the whole patient, in warm water, in which case these effects and movements may be attained without the need arising for any apparatus other than the pool itself. There appear to me to be two further advantages to be gained by using the under-water method: first, that the warmth (98° F. generally) tends to relax spasm during the whole course of the treatment; and, secondly, that since no *sudden* movement, which might give rise to pain, is possible under water, the confidence of the patient, and consequently his co-operation, is gained even more rapidly than with the authors' rope-and-sling method.

The value of the method I advocate is abundantly shown in the treatment of those very chronic cases of painful osteo-arthritis of the hip in which it is often believed, prior to treatment, that ankylosis with considerable adduction and shortening has taken place. I would further point out that this method has been used for years with considerable success at Bath in the treatment of spastic paralysis, which the authors also mention as an indication for their methods. The possibility of gaining access to the " deep pool " bath is no longer confined to those who are able to visit a spa; which is my justification for venturing to plead for the more general adoption of this form of treatment now that it can be obtained in many towns.—I am, etc.,

London, W.1, Jan. 15th. W. S. C. COPEMAN.

FOREIGN BODY IN THE NECK

SIR,—Dr. Alexander's case, recorded in the *British Medical Journal* of January 17th (p. 96), reminds me of an identical case which I reported in a paper on foreign bodies read before the Society for the Study of Disease in Children at their Brighton meeting three years ago. This patient also was a baby, aged 13 months, seen in consultation with Dr. Simpson. The swelling was only about seven days in forming and in softening. When opened under chloroform two small feathers escaped with the pus; and on the second day another small feather. These feathers corresponded with those of the baby's pillow. The wound healed quickly, and gave no further trouble.—I am, etc.,

GEORGE MORGAN,
Consulting Surgeon, Children's Hospital,
January 18th. Brighton.

HOG'S STOMACH IN PERNICIOUS ANAEMIA

SIR,—We have read Dr. J. F. Wilkinson's paper (*Journal*, January 17th, p. 85) with interest, but the data presented therein concerning the percentage of haemoglobin call for comment.

Dr. Wilkinson does not state the method or standard of the estimation, but we presume he uses the Haldane apparatus. Many of the observations in treated cases reveal a colour index below 1—for example, Case 57, Table 2, colour index 0.54, haemoglobin 62 per cent., red blood cells 5,750,000. This is at variance with our experience, using the flicker haemoglobinometer described by one of us (*Brit. Journ. Exp. Path.*, 1930, xi, p. 261). We have never seen a single instance of a low colour index in pernicious anaemia; the colour index varies directly with the change in the erythrocytic diameter. Further, the colour index persists above 1 when the haemoglobin is 110 per cent. or more, which is parallel to the observations of Price-Jones and others that the mean diameter is the last abnormality to disappear. It is probable that the inaccuracies of all colorimetric methods of estimating haemoglobin are chiefly responsible for the popularity of mean diameter estimation at the present time. We find it convenient to express our results in terms of the Haldane scale because the difference in the male and female erythrocyte count allows the respective colour

indices to approach unity in each case—0.98 for males and 1.04 for females. The average normal haemoglobin content as determined by one of us was found to be 118 per cent. for males and 104 per cent. for females, both over the age period 18 to 50. These flicker estimations agree, to within 3 per cent., with Williamson's monumental work with the spectrophotometer. (The relative fluctuations at different age periods were found to be identical with Williamson's observations.) We state these points concerning the normal in order to make clear that our present remarks are based upon results obtained with an instrument which is more accurate than any colorimetric method. Finally, we have observed that in some of our cases recovery is marked by a temporary rise in the haemoglobin to a percentage above the normal —for example, to 125 or more; this holds good for the erythrocytes also, which, we note, agrees with Dr. Wilkinson's observations. The phenomenon suggests to us that the final stage of recovery from a grave anaemia, pernicious or "secondary," is attended by a swing in the opposite direction due to the overaction or imperfectly opposed action of some factor held in abeyance during the active period of the disease.

Dr. Wilkinson gives ample evidence of the superiority of the hog's stomach over liver, but this is perhaps due not to any difference in the active principle contained in each, but to hog's stomach containing more of the anti-anaemic substance than liver. Duesberg (*Deut. med. Woch.*, Berlin, 1930, lvi, p. 1604) states that the active principle in both is probably the same, and he bases his conclusion, briefly, on the fact that liver, hog's stomach, and meat treated with normal gastric juice produce methaemoglobin in the blood. It is of interest also that after the termination of the reticulocyte response due to stomach preparation, Holböll (*Hospitalstidende*, Copenhagen, 1930, lxxiii, p. 825) obtained no new reticulocyte response by giving liver extract. Our criticism is directed solely to the lack of value of the haemoglobin estimations and colour indices, and is not intended to decry in any way Dr. Wilkinson's estimations of improvement based upon clinical observations, as we also observed the excellent effects produced by hog's stomach (extomak).—We are, etc.,

Salford Royal Hospital, Jan. 19th. C. S. D. DON.
C. E. JENKINS.

GENERAL PRACTITIONERS AND ANTE-NATAL WORK

SIR,—I am pleased to see from Dr. Leslie Cronk's letter in the *Journal* (p. 118) that I was mistaken in stating that the Hampshire scheme does not provide for examination of the midwife's patient at the doctor's surgery; it does so in the exceptional cases in which the woman is unable to attend a clinic. Since this scheme was drawn up, the position has been altered by the issue of Memo. 156/M.C.W. (reported in the *Journal* of December 27th, 1930 (p. 1089)). A perusal of this document makes it clear that the Ministry of Health is now prepared to sanction schemes for ante-natal services which allow the uninsured woman who has engaged a midwife for her confinement to go to the doctor of her choice for the necessary examination, not only when there is no clinic available, but also because some may be reluctant to visit a clinic. It should now be possible to secure in every area the carrying out of the recommendation of the Maternal Mortality Committee that the person doing the ante-natal examination should be the person who would be called in by the midwife for abnormalities during pregnancy, labour, and puerperium.—I am, etc.,

Poplar, E.14, Jan. 17th. W. H. F. OXLEY.

MEMBERS OF THE ROYAL COLLEGE OF SURGEONS

SIR,—A report of the proceedings of the Council of the Royal College of Surgeons of England appears in your issue of January 17th. The College consists of about 2,000 Fellows and 18,000 Members. The Fellows alone elect the Council, which has autocratic powers. Three generations of Members, backed up by some of the most distinguished Fellows, and several Presidents and Vice-Presidents of the College, have asked for some representation on the Council, so that the views of the 18,000 Members on professional matters may be directly expressed.

At forty-two consecutive annual meetings of Fellows and Members a resolution to this effect has been carried almost unanimously. Last year the College Council, in reply to such a resolution, answered that it had no evidence before it that any considerable number of Members supported this demand—in spite of nearly a century's consistent and persistent agitation to this end. In response to this statement the Society of Members of the Royal College of Surgeons of England took a poll of 12,600 Members—the financial reasons for so limiting the Members polled were fully explained to the President at the last annual meeting (November, 1930). The result was: Votes in favour, 6,938; Against, 156. It will be observed that considerably over 50 per cent. voted. Those experienced in professional voting will recognize that this is well above the average.

Completely ignoring this convincing vote, the Council, as stated in your last issue (p. 122) recited a number of oft-repeated platitudes, concluding by complacently stating that these various functions were well discharged by the governing body as now constituted. It further claims to be acting "not only for the benefit of the Members and Fellows, but the whole profession throughout the Empire," and that its view on this question is endorsed by its electorate—the Fellows. It is not stated that this "electorate" consists of only 2,000 Fellows in a corporation of 20,000, or that a very large number—nearly one-third—of the Fellows voted in favour of giving a voice to the Members. The rejection in this autocratic fashion of the reasonable claim of Members to have some four to six of their number added to a Council of twenty-four Fellows will not be likely to commend itself to the 18,000 Members of this great College.—We are, etc.,

ERNEST E. WARE,
President,
REDMOND ROCHE,
Vice-President,
Society of Members of the College.

London, Jan. 18th.

GLYCERIN AS A SURGICAL DRESSING

SIR,—I have read with great interest Dr. Kyle's letter on the use of glycerin for wounds (January 10th, p. 75). Perhaps I might mention that the addition of a certain amount of glycerin to perchloride of mercury lotion takes away from it the roughening effect on one's hands, which is such a drawback to the use of perchloride. But why does Dr. Kyle describe magnesium sulphate as hygroscopic? After reading his letter I weighed out 60 grains of magnesium sulphate, and spread it on a piece of dry paper, and left it exposed to the damp air of my unheated dispensary for four days. This morning I found it and the paper quite dry, and discovered that it still weighed neither more nor less than 60 grains.—I am, etc.,

Yattendon, Berks, Jan. 15th. F. A. BRODRIBB.

CAMBRIDGE DIPLOMA IN MEDICAL RADIOLOGY

SIR,—In view of various rumours as to the discontinuance of the Cambridge Diploma in Medical Radiology and Electrology, I should be grateful if you will let me draw attention to the following recommendation, which was sent from the Faculty Board of Medicine to the Senate on November 11th, 1930, and was passed by the Senate at a Congregation held on December 19th, 1930.

"The Faculty Board have had under consideration the annual report of the Committee for Medical Radiology and Electrology, as well as other information relating to the Diploma. The Board are convinced by the evidence laid before them that the Diploma continues to meet a real need, and that the standard of the teaching and of the examination is satisfactory. The financial position also is satisfactory.

"The Board therefore are of opinion that the Diploma should be re-established for a period of three years, but that, in view of the rapid growth in allied subjects, the position and scope of the Diploma and the arrangements made with the British Institute of Radiology should be reviewed before the expiration of that period."

—I am, etc.,

Medical School, Cambridge, Jan. 13th. G. STEAD, Secretary for the Diploma.

Obituary

JAMES A. ADAMS, M.D., F.R.F.P.S.

Consulting Surgeon, Glasgow Royal Infirmary

Dr. James A. Adams died in his seventy-fourth year on December 28th, 1930, at Shandon, Dumbartonshire, where he had been living for the past three years. His retirement was preceded by illness, and it was a matter of great regret, both to himself and to his colleagues, that he found himself compelled to resign his appointments and to give up practice. He maintained his interest in medical affairs to the end, making a last public appearance on November 30th at the service in Glasgow Cathedral in commemoration of Maister Peter Lowe, the founder of the Royal Faculty of Physicians and Surgeons of Glasgow.

Dr. Adams was the son of Dr. James Adams, a very popular and well-known doctor in Glasgow, and was the fifth Dr. Adams in direct descent from Dr. A. M. Adams, a portrait of whom, dated 1790, is still in the possession of the family. From this ancestor there sprang two main branches of the family—the Adams of Glasgow and the Maxwell Adams of Lanark. A member of the family, Dr. Maxwell Adams (*quartus*), in a brochure entitled a "Dynasty of Doctors," claims to be able to trace no fewer than sixteen members of the family all more or less connected with the profession of medicine. The only other dynasty comparable with this in Scotland is that of the Marshall and Cowan family, whose genealogical tree is traced through seven generations.

James Adams was a distinguished student in the University of Glasgow, graduating M.B., C.M. in 1878, with commendation, and in 1881 M.D. with honours. He became a Fellow of the Faculty of Physicians and Surgeons of Glasgow in 1878. The year 1878 was financially disastrous in Glasgow, as at that time the City of Glasgow Bank failed. Dr. Adams's father was a moderately large shareholder, and as these were the days before the Companies Limited Liability Act he found himself liable in many thousands of pounds to the depositors. Financial conditions, therefore, of necessity altered the professional outlook and future of the family. A young man whose student career had been of promise would naturally, with the support and influence of a father already a leader in the medical profession, look forward to preparation for specialism in some form as his future. That preparation began in the anatomical department of the University, where Adams was demonstrator under Professor Cleland, and in the Royal Infirmary, where he was surgeon to out-patients; in order to help to retrieve the family fortunes, however, he plunged into general practice with his father in the West End of Glasgow.

The subject of his thesis for M.D., "Certain anatomical relations between abscess of the brain and aural disease," was probably prompted by a discussion in the Medico-Chirurgical Society of Glasgow on cerebral abscess and its association with diseases of the ear, introduced by Dr. Thomas Barr, Glasgow's chief authority on otology. Apparently a great deal of interest was aroused; Macewen was in close association with Dr. Barr, and was then beginning his brilliant work which, seven years later, formed the subject of his epoch-making lecture to the British Medical Association at its Glasgow Meeting in 1888. Dr. Adams's research went to show that there are "anatomical peculiarities of structure in the organ of hearing which differ in the infant and in the adult, and which explain the greater frequency of abscess of the brain in adult life as originating from disease of the ear. Under certain conditions there is an abnormal state of the cerebral circulation which admits of a direct vascular connexion between the ear and the brain." This work was a very substantial contribution to the whole subject of cerebral abscess in its relation to otitis media, and cleared the way for establishment of the pathology of the disease on a secure anatomical basis. Again, in March, 1882, at the Medico-Chirurgical Society, he pointed out the vascular relations of the middle ear and mastoid cells and the brain, and, it seems to us, anticipated some of the work of Macewen and Horsley in urging the operation of trephining the mastoid process in cases of aural disease where head symptoms had appeared even in the slightest degree; and in the same contribution he advocated the opening of the mastoid antrum in cases of chronic otitis media, a procedure which afterwards became a matter of everyday practice. His anatomical studies led him to suggest the advisability of shortening the round ligaments through incisions over the inguinal canals in the treatment of uterine displacement. This "new operation for uterine displacement," published in the *Glasgow Medical Journal*, June, 1882, soon became known as the Adams-Alexander operation, as apparently the idea had occurred synchronously to two men. Adams was very careful to give Dr. William Alexander of Liverpool all the credit of priority in publishing successful cases of the operation, though he pointed out that for eighteen months previous to Alexander's publication he had been teaching the operation and discussing it with his colleagues. Papers on "Diaphragmatic hernia," and on a case of "Voluntary dislocation of the hip and jaw," also gave him excellent opportunities for anatomical discussion.

With his appointment to the Royal Infirmary, operative surgery became his chief interest, and he found little or no time to publish. In 1895 he had the distinction of performing the first successful pylorectomy for malignant disease in Scotland. The case is fully recorded in the *British Medical Journal* of April, 1896, where the details of technique are fully set forth. His publications show that Dr. Adams possessed, in considerable degree, originality of thought in the application of surgical anatomy, and it is in a measure unfortunate that the exigencies of practice and the strenuous routine work of surgeon to a large hospital like the Glasgow Royal Infirmary consumed the time and energy that might have been given to surgical research. He held the post of surgeon for the long period of twenty-seven years, carrying on in the years of the war, even after his term of office had, through age-limit regulations, come to an end. Other war

service was generously given as surgeon to the Princess Louise Hospital for limbless sailors and soldiers.

Dr. Adams received high honour from his professional brethren, as became one who had a long professional tradition to uphold, and was himself a keen and loyal doctor. In 1911 he was elected president of the Royal Faculty of Physicians and Surgeons of Glasgow; he conducted the monthly meetings with skill and geniality, and counselled wisely in committee. From 1920 to 1928 he was the Faculty's representative on the General Medical Council, where his knowledge of medical education must have been of great service. When he retired from active duties at the Royal Infirmary he was made an honorary consulting surgeon and a member of the board of managers. Not only the medical, but the social world of Glasgow, recognized him as a notable personality. In his prime he was an enthusiastic Volunteer. An original member of the university contingent of the 1st L.R.V., he transferred with it to the 5th Scottish Rifles, where he rose to the rank of lieutenant-colonel, and was awarded the Volunteer Decoration. He was a welcome member in officers' mess or medical company, for no one was more famous for his fund of anecdotes, racily told, and apt in allusion. His ordinary talk abounded in good-humoured chaff, and he had ready methods of turning aside the ouslaughts of the irate and the irrationality of the crank.

"Jimmy Adams" will long be remembered in Glasgow as a genial kindly man, a well-liked and trusted doctor, a sound practical surgeon, and a worthy bearer of the torch of medical light.

J. P.

ETHEL BENTHAM, M.D., M.P.

Consulting Physician, Memorial Baby Clinic, North Kensington.

We regret to record the death of Dr. Ethel Bentham, M.P., which took place on January 19th, due to heart failure following a severe attack of influenza.

Dr. Bentham was born in London seventy years ago. Her father, William Bentham, J.P., was well known in the Society of Friends, of which society she remained a faithful member throughout her life. She spent her early school years in Dublin, and, resolving to become a doctor, studied at the London School of Medicine for Women, at the Rotunda Hospital, Dublin, and also in Brussels and Paris, taking the triple Scottish qualification in 1894, and the M.D. degree of Brussels University in the following year. She began practice at Newcastle-on-Tyne, where she remained for about fourteen years, and then, coming to London, continued in general practice until recently. It was on her suggestion that the Baby Clinic and Hospital at North Kensington was founded in memory of Margaret MacDonald, wife of the present Prime Minister, and Mary Middleton, both of whom were her old friends and fellow workers. She became its senior medical officer, and was still consultant there at the time of her death. Dr. Bentham joined the British Medical Association in 1895 on commencing practice; in 1912 she was elected a member of the Executive Committee of the Kensington Division, and in 1921 she served on the British Medical Association Parliamentary Sub-committee. She was also a member of the Association of Registered Medical Women. At the inception of the National Health Insurance Act she became a member of the Panel Committee for the county of London, and for some time did very active work as chairman of its Finance and General Purposes Subcommittee. She had a seat on the old Metropolitan Asylums Board, and there strongly supported the reform of the casual wards.

Her public and political career began in Newcastle, where she interested herself in the constitutional movement for woman suffrage, and also became a zealous worker in the Labour movement, standing, unsuccessfully, for the city council. On coming to London she engaged in many forms of public work, and showed an interest, which with her was hereditary, in social problems in many directions. She sat for several years on the Kensington Borough Council, and was appointed a justice of the peace as soon as women were eligible for that office; in that capacity she interested herself particularly in lunacy cases and juvenile courts, and was herself a member of such a court. Her first attempt to enter Parliament was made at East Islington in 1922. She contested the constituency again in 1923 and in 1924, and finally, in 1929, gained the seat for the Labour party, being returned by a majority of 1,558 in a three-cornered contest. She was the first medical woman and also the first woman Friend to enter Parliament. In the House of Commons she was active without being conspicuous; although rarely speaking in debate, she did much quiet work behind the scenes. One of her longest speeches was on the Mental Treatment Bill, whose introduction she heartily welcomed as a reform long overdue. She pleaded on that occasion for the renaming of the Board of Control, and for something to be done to create greater public confidence in that rather mysterious authority. The speech illustrated her quiet humour, which was never very far from the surface. She amused the House by recounting from her experience the story of a man discharged as cured from a mental hospital, who was discovered by an after-care visitor just about to cut his throat as he lay in bed. She prevented him effectively by calling out, "Not there, man; think what a mess you'll make. Come out and do it over the sink." Dr. Bentham's last speech in Parliament was to introduce the Bill which provides that British women who marry aliens shall retain their nationality. She was a member of the Select Committee on Capital Punishment, which recently reported.

This simple Quaker lady, whose only recreations were walking and music, had a frail physique, and one wondered sometimes at her vast expenditure of energy. She was not marked out for, nor was she very successful in, platform electioneering; her strength lay in quiet unobtrusive administrative work, and she was always glad enough that others should have the glory if only the thing itself were done. The hackneyed quotation about doing good by stealth received a fresh exemplification in her, as many poor families in Newcastle and in London, to whom she gave of her kindness and skill, could testify. It is stated that her last hours were brightened by an intimate letter sent to her by the Prime Minister directly he learned that her illness had taken a turn for the worse.

The remains were to be cremated at Golder's Green on Thursday morning; this to be followed by a public memorial meeting at Friends House, Euston Road, of which Dr. Bentham was a member. The interment was to take place at Jordans new burial ground on Friday.

THE LATE MR. MAURICE FITZMAURICE-KELLY

Mr. PAUL BERNARD ROTH writes: I feel that no obituary notice of the lamented Maurice Fitzmaurice-Kelly is complete without special mention of the part he took in introducing into England the circular amputation as an emergency operation for cases of severe gunshot wounds of the limbs. I am not sure but that he alone introduced it. Before he brought it to the notice of British surgeons we were all performing amputations on these cases, as they arrived from the front, according to civil usage, and with deplorable results. Flaps were marked out, cut, turned back; the muscles were stripped from the bone; the bone was sawn through four or five inches above the break; and the muscles and skin-flaps replaced and sutured. On the following day violent suppuration commenced in the freshly exposed surfaces, and in a great many cases death occurred as a direct result, I fear, of the operative proceedings. We were absolutely at a loss

to know what to do until there appeared in the medical press a letter from Fitzmaurice-Kelly, pointing out that what we were doing was entirely wrong, and that a circular amputation at the level of the injury, without exposing any fresh surface and without any suturing whatever, was the only way to save the soldier's life. Later, when all the fever had subsided and the inflammation had gone, we could amputate in the ordinary way at our leisure. We adopted his revolutionary proposal, and thereby thousands of lives were preserved. To my friends and myself at the time the operation was always known as the Fitzmaurice-Kelly amputation.

Universities and Colleges

UNIVERSITY OF OXFORD

An examination for a Radcliffe Travelling Fellowship of the annual value of £300, tenable for two years, will be held during Hiliary term, 1931, at the University Museum, commencing on Tuesday, February 24th, at 10 a.m. Candidates must have passed all the examinations required for the degree of Bachelor of Arts and for the degree of Bachelor of Medicine. The examination will occupy four days. Intending candidates should send in their names, addresses, qualifications, etc., to the Regius Professor of Medicine, University Museum, by Wednesday, February 11th.

UNIVERSITY OF CAMBRIDGE

The Appointments Committee of the Faculty of Medicine has reappointed Dr. A. E. Barclay of Christ's College as University Lecturer in Medical Radiology and Electrology for three years.

On the nomination of the Council of the Senate, Professor H. R. Dean, M.D., Master of Trinity Hall, has been appointed a member of the Dominion Students Hall Trust for the establishment of "London House," a hall of residence for British and Dominion students in the metropolis.

UNIVERSITY OF LONDON

The University Court, at its meeting on January 14th, accepted on behalf of the University the generous bequest of £4,000, free of legacy duty, from the late Miss Mary Ethel Sim Scharlieb, who died in 1926. The purpose of the bequest is the founding of a scholarship in memory of Miss Scharlieb's mother, the late Dame Mary Ann Dacomb Scharlieb, M.D., M.S., LL.D., to whose life interest the legacy was subject. The scholarship is to be called "The Mary Scharlieb Research Scholarship," and the conditions of award are to be determined by the University.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE

Post-graduate courses will be held at the College of Medicine, Newcastle-upon-Tyne, in January, February, and March. The courses will include diseases of infancy and childhood, midwifery, gynaecology, diseases of the eye, diseases of the throat, nose, and ear, diseases of the skin, and of neurology; the classes will meet weekly. A detailed syllabus will be sent on application to the Registrar. A general course in medicine and surgery will be held from April to June, and a fortnight's intensive course in September.

The Services

DEATHS IN THE SERVICES

Deputy Surgeon General Horace Ximenes Browne, R.N. (ret.), died at Thorncote, Higher Hove, Plymstock, South Devon, on November 22nd, 1930. He was educated at Bart's, and took the M.R.C.S. and the L.R.C.P.Ed. in 1878. Entering the Navy soon after, he attained the rank of fleet surgeon on August 11th, 1894, and retired with an honorary step of rank as deputy inspector-general on November 24th, 1910. He served as surgeon of H.M.S. *Condor* during the naval and military operations at Suakin in 1884-85, receiving the Egyptian medal, with a clasp for Suakin, and the Khedive's bronze star; and as staff surgeon of H.M.S. *Raleigh*, the flagship, when he served in the Naval Brigade under Rear Admiral Bedford, C.B., for the punitive expedition against the Chief Nanna of Brohemie, in the Benin River, resulting in the capture of the stronghold of Brohemie on September 25th, 1894, when he was mentioned in dispatches, and received the African general service medal with a clasp for Benin River, 1894.

VITAL STATISTICS FOR ENGLAND AND WALES, 1930

We are indebted to the Registrar-General for the following statement regarding the birth rates and death rates, and the rates of infantile mortality, in England and Wales and in certain parts of the country during 1930. The statement is issued for the information of medical officers of health. The birth rate and infantile mortality rate for London have been provisionally corrected for transfers.

ENGLAND AND WALES

Birth Rate, Death Rate, and Infantile Mortality during the Year 1930 (Provisional Figures)

	Live Births per 1,000 Population	Deaths per 1,000 Population (Crude Rate)	Deaths under One Year per 1,000 Live Births
England and Wales (on 1930 estimated population)	16.3	11.5	60
10[illegible] on	16.7	11.5	64
159 smaller towns (populations from 20,000 to 50,000 in 1921—on 1929 estimated population)	16.2	10.5	55
London (on 1929 estimated population)	15.7	11.4	59

The death rate for England and Wales relates to the whole population, but that for London and the two groups of towns to the civil population only.

The birth rate is the same as that for 1929, which was the lowest recorded. The death rate is 1.9 below that for 1929, and is the lowest on record, being 0.1 below the rate for 1923 and 1926—the previous lowest.

The infantile mortality rate is also the lowest on record, being 5 per 1,000 below that for 1928, the previous lowest, and 14 per 1,000 below that for 1929.

Medical News

The Hunterian Society of London will commemorate the 203rd anniversary of the birth of John Hunter by a banquet at the May Fair Hotel on Thursday, February 19th, at 7.30 p.m. The Lord Mayor and Lady Mayoress of London, and other distinguished guests, have accepted invitations to be present. The price of the dinner (12s. 6d., exclusive of wines) will be collected at table.

The Master and Wardens of the Society of Apothecaries are giving a Livery Dinner, to meet the Lord Mayor and Sheriffs of London, in the Society's Hall, Blackfriars, on Tuesday next, January 27th.

Under the auspices of the People's League of Health Sir Robert Armstrong-Jones will give a lecture on March 2nd in the Town Hall, Woolwich, on mental hygiene.

A joint meeting of the Sections of Surgery and Pathology of the Royal Society of Medicine will be held on Wednesday, February 4th, at 8.30 p.m., for a discussion on "Indications for, and the value of, the intravenous use of germicides."

The annual general meeting of the Association of Public Vaccinators of England and Wales will be held at the offices of the Society of Medical Officers of Health, 1, Upper Montague Street, W.C., on Friday, January 30th, at 3.30 p.m. All public vaccinators are cordially invited.

A joint meeting of the Society for the Study of Inebriety and the Psychiatry Section of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Tuesday, March 10th, at 8.30 p.m., to discuss the prevention and treatment of drug addiction (excluding alcoholism). The openers representing the Society for the Study of Inebriety will be Dr. William Brown and Dr. Macdonald Critchley. The openers representing the Psychiatry Section will be Dr. Edward Mapother and Dr. F. G. Laughton Scott.

The National Council for Mental Hygiene has arranged the following lecture-discussions, to be held at 11, Chandos Street, Cavendish Square, W., on Thursdays, at 5.15 p.m., from February 12th to March 19th inclusive: modern marriage and its problems, Mrs. Neville-Rolfe; psychology of education, Professor J. E. Marcault; psychology of dreams, Dr. J. R. Rees; psychology of sanity, Dr. J. Burnett-Rae; psychology of suicide, Dr. H. Crichton-Miller. Dr. W. A. Potts; psychology of punishment, Tickets, 1s. 6d. each, or 7s. 6d. for the course, may be had from the secretary of the Council, 78, Chandos House, Palmer Street, S.W.1, or at the doors.

Three lectures, arranged by the Food Education Society on "Food and food habits, and their connexion with rheumatism, cancer, and other chronic diseases," will be given by Dr. R. Ackerley at 29, Gordon Square, W.C. (entrance in Gordon Street), on Wednesdays, February 11th, 18th, and 25th, at 5.30 p.m. Admission free.

The House of Commons resumed after the Christmas Recess on Tuesday, January 20th, when the China Indemnity (Application) Bill was read a second time. The report stage of the Education (School Attendance) Bill was down for Wednesday.

Dr. Alfred Cox's speech on the medical aspects of State insurance in Great Britain, made last summer at the congress known as the Journées Médicales de Bruxelles, has been published in French in the *Bruxelles-Médical* of January 11th.

At the recent formal opening of the nurses' home extension of the Royal Victoria Infirmary, Newcastle-upon-Tyne, Sir Walter Runciman announced his intention of increasing his contribution to the movement from £20,000 to £25,000. The new wing, which is to be named after Sir Walter Runciman, will provide accommodation for 150 nurses who have hitherto had to live outside the hospital.

The propaganda committee of King Edward's Hospital Fund for London (7, Walbrook, E.C.4) invites applications for illustrated lectures on the work of the London voluntary hospitals, to be given to schools and institutions during the Easter term. These lectures are being given on the committee's behalf by doctors, nurses, hospital secretaries, and others experienced in hospital work.

At the January meeting of the Central Midwives Board for England and Wales the secretary reported that the College of Nursing had agreed to undertake the conduct of a course of instruction in the subjects of the midwife-teachers' examination, and that the College and the Midwives' Institute had arranged that the Institute should co-operate in the conduct of the course.

A Bill to be introduced into the Tanganyika Territory Legislative Council provides for the recognition in the Protectorate of a medical diploma granted in any part of the world. Under the present law the only persons entitled to registration in Tanganyika are the holders of qualifications recognized as entitling to registration in the United Kingdom. Similar provision is made as to the registration of dentists.

The next International Congress of Oto-Rhino-Laryngology will be held in Madrid in 1932, when the subject for discussion will be scleroma, introduced by Professor Lasagna of Parma, Professor Burack of Minsk, and Professor Wisckovki of Bratislava.

The late Dr. James Macfee of Auchterarder has left personal property of the value of £105,861. He has bequeathed £10,000 to the National Lifeboat Institution and £3,000 to the Perth Royal Infirmary.

As the result of a report drawn up by Professor Guillain and Dr. Souques, the Académie de Médecine has expressed the opinion that public exhibitions of hypnotism are undesirable, and should be prohibited.

The gold medal of epidemics has been conferred posthumously on the late Dr. Ernest Conseil, director of the Health Office of Tunis, and collaborator with Dr. Charles Nicolle in his work on typhus, cholera, and plague.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Late Effects of Vasectomy

"J. W. L." desires to know what are the late effects of vasectomy. Do the good effects claimed by Steinach (in 1923) continue?

Writing with Left Hand

"SINISTRAL" sends the following query: A boy of 9 writes with his left hand, but uses his right for other purposes. Should he be required to write with his right hand, and, if so, what is the risk of producing stuttering?

Blushing

Dr. W. L. GILLBARD writes: I wonder if any of your readers can tell me of a successful cure for blushing. I have a patient, a young man of 24, who is much distressed by a habit of blushing when among strangers. Sometimes he will flush for no apparent reason when in the company of his own family, but it more commonly occurs in public vehicles, restaurants, and places of entertainment.

Hystero-epilepsy?

Dr. H. V. CRABTREE (Exeter) asks for suggestions for diagnosis and treatment in the case of a married woman, aged 30, who suffers from attacks of an apparently hysterical nature. They occur only indoors, and may last from five minutes to three hours or more. The attack, of which she has foreknowledge, starts with a violent shivering, during which she tries to prevent herself from losing consciousness. Sometimes she is successful, and the attack passes off, at other times she lapses into a semi-conscious state, with struggling movements of the limbs. Her eyelids close, and she repeats conversations (always in the correct order of their occurrence) which she has had for some years back, and advancing up to the moment when the attack commenced; there is then another violent shudder, she opens her eyes, and the attack is over. During the attack, if the lids are forced open, the eyeballs are found to be turned downwards, not upwards as in sleep, and there is a tendency for them to roll. Bromides, valerian, and general tonics have been tried; and during her pregnancy the patient has had fewer and shorter attacks.

Dalrymple's Sign

Dr. W. R. BETT (London, W.4) writes: Eponyms are like spider's webs; they entangle the weak but are broken by the strong. The weakness of historical curiosity has lately led me to trace the legitimate or illegitimate birth of thyroid eponyms. Trying to discover the original description of Dalrymple's sign I must confess myself defeated. I cannot rest satisfied with the contemporary description by W. White Cooper in the *Lancet* (1849, i, 551) of Dalrymple's observation: "The eyes, being greatly protruded, were nearly denuded of the protection of the upper

lid by a constant and powerful spasm of the levator palpebrae superioris, which drew the lid so far upwards and backwards that much of the sclerotic above the cornea was visible. This spasm of the levator of the lid is not uncommon in nervous and hysterical females, and is frequently associated with other irregular muscular actions, such as chorea. The expression given to the countenance by this protrusion of the globes, and the unnaturally elevated lid, is very peculiar, and the aspect is that of the wildest terror." If one of your readers can quote Dalrymple's own description of what is now known as his sign, the writer of this note would be his debtor.

Nail Biting

"B. S." writes: In reply to "M.B." (January 3rd, p. 427), I would suggest persuasion, and education in the proper care of the hands. Without making any special mention of the subject, let the child see you cut your nails regularly, brush them, and wash the hands, and encourage him to do the same. Inspect his hands frequently to see if there is anything to cut, but without any word of reproach. I have often found that a child bites his nails on account of discomfort, and this is relieved by suggesting at once that he should wash his hands. He should be given free use of a soft nail brush. Children are usually ashamed of the habit, and will thankfully accept some help in overcoming it. It is a good plan, if they mention it, to say calmly, "Oh! I used to do it, but I don't now." Children are easily led if the leading is not too obvious.

Income Tax

Motor Car Expenses

"R. D." changes his car every year—as do a number of other practitioners—and the cost of replacement this year was £375 - £260 = £115. The inspector of taxes refuses to allow the deduction of that sum as "obsolescence" on the ground, apparently, that the car disposed of was not "obsolete."

*** In such circumstances the simplest course is to claim neither "depreciation" nor "obsolescence," but that the cost of replacement of the car is a professional expense of the year in which the exchange was effected. If, however, depreciation has been claimed for the year of assessment in question then "cost of replacement" cannot be claimed as well, and the best course would be for the "depreciation" claim to be withdrawn or cancelled, and so clear the way for the more direct claim. So far as "obsolescence" is concerned the inspector of taxes has some legal authority for his objection, though the judicial decision on the point was given on somewhat special facts, and does not appear to be applicable—so far as our knowledge goes—to the circumstances of this case.

LETTERS, NOTES, ETC.

Medicine and Public Economy

Sir ERNEST GRAHAM-LITTLE, M.P. writes: It will be universally agreed that the most urgent need at the present moment is economy, both in national and local public expenditure. The medical profession played a nobly patriotic part in the great war, and the present crisis threatening our country is of nearly equal gravity; there can be no doubt that the profession will wish to take its share in promoting any campaign for enforcing public economy. A group of public men, drawn from all parties and calling themselves "The Friends of Economy," are about to inaugurate such a campaign by a public meeting to be held in the Great Hall, Cannon Street Hotel, London, E.C., on Tuesday, January 27th, at 3 p.m. The chairman will be Mr. Edward Charles Grenfell, M.P. for the City of London, and the meeting will be addressed by Viscount Grey of Fallodon, Sir Robert Horne, and Sir Ernest Benn. As the only medical man engaged in active practice included in this group (the list of which I enclose), I am entrusted with the duty of approaching medical journals in the hope of enlisting the support of the profession for this movement.

Removal of Adenoids

Dr. C. CONOR O'MALLEY (surgeon, ear, nose, and throat department, Central Hospital, Galway) writes: In his interesting article on removal of adenoids Mr. O. Popper draws attention to an important point—namely, sharpness of the curette blade. With the right pattern, trauma with stripping of the mucous membrane should occur only when the instrument is a blunt scraper. Since the removal of adenoids is a cutting operation I have always felt that the curette is a more sensitive instrument when held as one holds a scalpel or dinner knife. One would think that skill in a surgical manipulation must be in some degree regulated by one's practice at similar manœuvres in everyday life. Personally, I have rarely seen difficulty in making a clean sweep of the adenoid mass with the StClair Thomson curette. My only difficulties have been caused by using faulty instruments, unblushingly called "StClair Thomson pattern" by various makers, and supplied by hospital contractors. It would be a boon to the profession, and only fair to the original designers, if something could be done to make manufacturers realize the importance of correct design when marketing surgical instruments.

Mr. O. POPPER writes: I am afraid that a transposition of type, occurring in my paper in last week's issue, has rendered the affected portion unintelligible. On page 93 (second column) the stages of the operation are outlined. The printer's error affects (2) and (3) only, but as all the movements merge into one another I would be most obliged if you could reprint these stages *in toto*, as follows: (1) The post-nasal space is carefully examined with the finger to determine the size of the mass and extensions. Under good illumination the instrument is inserted behind the soft palate and pushed upwards until it touches the vault. (2) The handle is dropped towards the chest, so that the back of the cage rests against the posterior edge of the nasal septum and the blade engages the upper portion of the adenoid mass in the vault. (3) Applying moderate pressure, the blade is swept down the post-nasal wall by raising the handle towards the face. (4) When the cage appears from behind the palate it is swept out of the mouth. This detaches the adenoids, and the whole mass will be found in the cage. The movements are, of course, continuous.

Pathological Museum at the Eastbourne Meeting

In referring to the organization of a museum of scientific exhibits and pathological specimens in connexion with the ninety-ninth annual meeting of the British Medical Association, to be held at Eastbourne in July next, we mentioned in our issue of January 10th (p. 67), that a proposal had been made to gather together "a series of exhibits—*x*-ray and other photographs—relating to milk-borne human diseases." We have since been informed that this description should have been: "a series of exhibits relating to milk-borne diseases *and* a series of *x*-ray and other photographs."

Disputing the Bill

Many of our readers must have followed the interesting correspondence between Mrs. X and Dr. Y in last week's *Punch*, and we are prompted to offer to "Woon" the thanks of a much-exploited profession for his work in another Good Cause. Through the interlocutory extravaganzas of Great and Little Dithering, the nocturnal inculcations by telephone, and the irrelevant questions about the practitioner in attendance on a cousin, there runs that vein of agony which many doctors know so well but few express. If "Medical Details" were reprinted and sent out in leaflet form with every doctor's account it might act as a deterrent to the ungrateful and the demurring. And as a title, the advice of Mr. Punch himself might be adapted: To those about to query—Don't!

Medical Golf

The annual general meeting of the Sheffield Medical Golfing Society was held in December last. The society now has a membership of sixty-eight. Five matches have been played—three being won, one lost, and one drawn. The winner of the society's cup for 1930 was Dr. F. N. R. Price, and the runner-up Dr. A. B. F. Rodger.

Vitamin Deficiency

A pamphlet on *The A and B Avitaminosis Disease of Sierra Leone* has been privately printed for the author, Dr. E. Jenner Wright, who informs us that he will be pleased to supply copies to any reader particularly interested in the subject. His address is 11, Ridge Hill, Golder's Green, N.W.11.

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, 50, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at at pages 48, 49, and 50.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 23.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

72 Treatment of Non-tuberculous Pulmonary Conditions

J. ALEXANDER and W. W. BUCKINGHAM (*Journ. Amer. Med. Assoc.*, November 15th, 1930, p. 1478) discuss the treatment of non-suppurative pneumonitis, abscess, and bronchiectasis. Suppurative pneumonitis not infrequently complicates operations, pneumonia, and infections of the mouth and sinuses. The lesion of the earliest stage is usually a purulent infiltration of the alveoli and interstitial tissue of the lung, with an associated infection of the bronchioles and small bronchi. The suppurative infiltration may be excavated by necrosis to become an abscess or multiple abscesses, or even a gangrenous extension; the condition may also proceed to bronchiectasis. The location of the principal lesions in the parenchyma determines abscess formation, and in the bronchial walls a bronchiectasis; it is important to prevent the sequels by curing the initial lesions. In the early stages of suppurative pneumonitis medical treatment is best, and often cures. If it fails, surgery frequently offers chances for cure if an operation is not unduly delayed. The most useful medical and surgical methods are: sanatorium regimen; frequent postural drainage; elimination of mouth and sinus infection; intravenous injections of neoarsphenamine; bronchoscopic removal of foreign bodies and secretions; artificial pneumothorax; temporary or permanent interruption of one phrenic nerve; extrapleural pneumolysis and thoracoplasty; drainage of an abscess; and lobectomy. The selection of the best procedure is an individual consideration; the simplest measure likely to suit the particular patient should first be chosen. The authors enumerate the succession of methods which they have found of value in the various types of suppurative pneumonitis.

73 Idiopathic Pyrexias

J. TROISIER (*Ann. de Méd.*, November, 1930, p. 480) mentions various conditions in which an unaccountable slightly elevated temperature occurs. Continued fever is often noted in children following cured infections of the rhinopharynx and enterocolitis, and in nervous children. The temperature is also sometimes raised in fatigue, and in women for some days before the menstrual periods. A case is recorded of a man, aged 31, who had been under observation for many years and who had always shown a temperature higher than that usually regarded as normal. His average morning rectal temperature was 100.5° F., and the evening rectal one nearly 101° F.; the axillary temperature was three-tenths of a degree lower. The man complained only of slight lumbago, being otherwise apparently healthy, and there was no evidence of nervous disequilibrium such as hysteria, or of endocrine disturbance. He stated that he has always had a high temperature, and that his father also had a habitual temperature of 104° F. Troisier considers this a case of congenital high temperature, transmissible by direct heredity from father to son, its pathogenesis being quite hypothetical. He points out that the homothermal mammals (dogs, rabbits, guinea-pigs, oxen, etc.) have a normal temperature of about 102° F., and that the horse and the chimpanzee have the normal human temperature of 98.4° F. The author adds that in cases of prolonged fever the possibility of a congenital high temperature being the cause should be considered.

74 Endocrine Factors in Migraine

E. F. HARTUNG (*Med. Journ. and Record*, November 19th, 1930, p. 497) considers migraine to be a manifestation of pituitary hypofunction. While in ordinary circumstances the pituitary gland is adequate, it suddenly enlarges with the call for increased activity under physiological or emotional stress and produces migraine. The condition is associated with the onset of puberty or occurs after the climacteric has passed, at which times the activity of the endocrine glands is increasing or subsiding. Acting upon this assumption, it has been clinically demonstrated that an attack of migraine may be abated by the hypodermic administration of adrenaline or of pituitary substance orally. In an experience of fifty cases hypodermic injections of anterior and posterior lobe pituitary or whole gland extract were given twice a week for the first month and thereafter once a week as long as required. In oral administration one-twentieth to one-half grain doses of the whole powdered gland were administered, such relatively small doses being necessitated by the fact that larger doses occasionally cause headache even in normal persons. Failure to procure relief occurred in only three instances; twelve patients were markedly improved, and the attacks in the remaining thirty-four were greatly reduced in frequency and severity. Hartung remarks that gastro-intestinal irregularities, focal infections, and refractive errors must be corrected, and a low carbohydrate diet be enforced, while the patient is kept within his constitutionally low fatigue threshold. Although the numbers thus treated are too few to allow of a final conclusion being drawn, the author considers that endocrine therapy offers the most encouraging results in the treatment of migraine.

75 Benign Lymphocytic Meningitis

According to V. DAUNA (*Thèse de Paris*, 1930, No. 320), who records 22 cases in patients aged from 4 to 45 years, all of whom made a complete recovery, this condition is characterized by an infectious state, accompanied by a meningeal syndrome, in which lumbar puncture shows the presence of an abundant lymphocytosis. The affection may occur in either a sporadic or an epidemic form. In a certain number of cases benign lymphocytic meningitis is due to acute poliomyelitis, epidemic encephalitis, or well-defined diseases such as herpes, mumps, and spirochaetal jaundice, but in some cases the etiology remains obscure. The diagnosis is extremely difficult, especially from tuberculous meningitis, so that in any case of lymphocytic meningitis resembling tuberculous meningitis, but not definitely proved to be so, the prognosis should be guarded, and the patient's condition should not be regarded as hopeless.

Surgery

76 Treatment of Skin Cancer

J. J. ELLER and E. C. FOX (*New York State Journ. of Med.*, November 15th, 1930, p. 1344) urge the importance of early diagnosis and judicious treatment of dermatoses that may become cancerous. Of the many skin diseases which may terminate in malignant neoplasm, syphilis, leucoplakia, radio-dermatitis, senile and seborrhoeic keratoses, kraurosis vulvae, lupus, and tuberculides have to be suspected, and a preliminary biopsy (except in melanoma) is advised in order to determine the degree of malignancy and the approximate radio-sensitivity or radio-resistance. Many chronic skin diseases in patients over 40 years old are basal cell epitheliomata; they develop frequently on a seborrhoeic keratosis, differ greatly in appearance, and may occur in any region, but approximately 80 per cent. are situate about the head and neck. The majority of early cases are curable; failures occurring in chronic cases exhibit invasion of bone or cartilage. The authors used unfiltered x rays for the majority of their basal cell epitheliomata. Lesions involving the aural or nasal cartilages were destroyed completely by electro-coagulation or excised with the high-frequency knife,

followed by unfiltered x rays or an equivalent local application of radium or radon. In prickle-cell epithelioma the tumours grow more rapidly and metastases occur earlier; they are usually more resistant to radiotherapy. Early prickle-cell tumours of the trunk can be treated successfully by radiation alone, but it is often advisable to excise the lesion or to employ electro-coagulation, followed by radium or radon. Electro-coagulation of tumours in cartilaginous areas (which are very resistant to irradiation) is advised, followed by irradiation. In lip epitheliomata the papillary type responds most rapidly to radiotherapy, while the infiltrating form is most dangerous on account of early metastasis. Penile epithelioma constitutes 1 to 3 per cent. of all cases in men; basal squamous-cell epithelioma is more malignant than the foregoing and is more resistant to radiotherapy. The prickle-cell lesion is more common in penile cases and responds well to radiotherapy in early cases. When Buck's fascia is involved the lesions react less readily, and electrothermic amputation may be required. Melanocarcinoma and melanosarcoma are both extremely malignant and require extensive excision with the high-frequency knife. In Paget's disease of the nipple, ablation of the breast, followed by irradiation, is advised. Lymphosarcoma of the skin responds well to irradiation, but in intensely hard chronic tumours surgical treatment should precede it. In early sarcoma the best results are obtained by a combination of radiotherapy and surgery; the dose required is similar to that given in prickle-cell epitheliomata. More resistant tumours require surgical excision and subsequent radiotherapy.

77 Traumatic Perforation of the Small Intestine without External Injury

S. POLIZZI (*Rinascenza Medica*, December 1st, 1930, p. 575) reports the case of a man who was kicked in the lower right quadrant of the abdomen about three hours after a meal. A few hours later he vomited food but no blood. During the night the pain increased, the vomiting became bilious, and the temperature rose. When admitted to hospital he was obviously very ill and his pulse was 120. There was abdominal rigidity and tenderness on palpation over the right lower quadrant, but no sign of external injury. Laparotomy was immediately performed. Although the appendix was unhealthy, it did not seem sufficiently so to account for the peritonitis, and there was no perforation. Appendicectomy was performed, and on further search a perforation was found in the small intestine about 30 cm. from the ileo-caecal valve. The perforation was sewn up and the patient made a good recovery. Polizzi suggests that the perforation was probably caused by the intestine having been squeezed against the hard vertebral column.

78 Operations on Diabetic Patients

L. R. GROTE and M. FLESCH-THEBESIUS (*Zentralbl. f. Chir.*, December 5th, 1930, p. 3026) comment on the great assistance brought by insulin to the surgical treatment of diabetic patients, and report three cases in detail by way of illustration. In the first case a woman, aged 47, who had had diabetes for twenty-four years, was successfuly submitted to an operation for the removal of a large uterine fibromyoma which had resisted irradiation treatment. Vaginal panhysterectomy under ether anaesthesia was performed, and the patient made an excellent recovery. The second patient was a man, aged 30, who was operated upon for chronic appendicitis, and the third patient, a woman aged 52, was suffering from severe furunculosis, the prognosis being very grave. In spite of there being no fewer than twenty abscesses, careful insulin treatment enabled a complete cure to be obtained by surgical intervention. The authors mention other cases in support of their contention that it is possible to control the metabolism appropriately before and after the surgical treatment of diabetic patients. For the operation, chloroform anaesthesia is inadmissible; lumbar anaesthesia is popular in America, and the present authors obtained good results from the intravenous injection of pernocton.

Therapeutics

79 Rational Treatment in Arterial Hypertension

S. WEISS and L. B. ELLIS (*Journ. Amer. Med. Assoc.*, September 20th, 1930, p. 846) maintain that no satisfactory drug treatment has yet been evolved for arterial hypertension. Experimental studies have shown that this condition, which may be functional at the outset, is the physiological and necessary response to decreased permeability of the arteriolar and capillary systems; they agree that the etiology is obscure, and in particular hold that there is insufficient proof of its relation to any local circulatory disturbance in the kidneys. Graphic proof of the transient nature of nitrite action is shown, and the danger of cerebral and other catastrophes resulting from sudden pressure reduction is mentioned. The most hopeful course is to induce the hypertensive patient to lead a rational life. All excesses of diet and exertion are naturally to be avoided; a proper amount of ordinary sleep is essential, and an additional period of afternoon rest is highly desirable. The reduction of all protein intake to 10 per cent. of the total calorie value of food taken daily is advised. Tobacco is not contraindicated, except in cases where its use is found to cause a definite increase in tension. A daily action of the bowels without straining is important. The use of sedatives of the barbituric acid group has been found of great value as an adjunct to general management, especially in the case of highly strung and excitable persons. Warm baths at not less than 34° C. are helpful. It is, above all, essential to consider the temperament of each patient, and to avoid the creation of "blood pressure phobia" by too great insistence on the condition. Experience has revealed that with the use of general measures, with or without accessory drugs, a proportion of the patients will improve as regards their symptoms and the recorded pressures; others will show great improvement generally, and be enabled to lead useful and comparatively active lives, without any measurable change in their tension. Some patients will not manifest any objective or subjective change, and will inevitably progress unfavourably. The tendency of certain patients to spontaneous improvement must not be forgotten. In all cases the eradication of obvious focal sepsis is indicated, not because it has any proved association with hypertension, but because, like syphilis and other infectious processes, it predisposes to vascular sclerosis.

80 The Haemostatic Action of Congo Red

During the course of Wedekind's researches on carbon and Congo red in pulmonary tuberculosis, the haemostatic properties of the latter substance were accidentally discovered. T. WEDEKIND, J. BECKER, and B. WIENERT (*Münch. med. Woch.*, November 28th, 1930, p. 2049) have therefore explored the clinical use of Congo red as a haemostatic in various cases of haemorrhage. A sterile 10 per cent. solution of Congo red (Grübler) was used, 5 to 10 c.cm. being injected intravenously, the injection being repeated if necessary; no untoward effects were ever observed although 50 conditions were treated, including haemoptysis, bleeding from teeth sockets, menorrhagia, and haematuria, and in the great majority of these the haemorrhage was arrested in from half an hour to six hours. Foreign bodies, especially electro-negative colloidal suspensions, have been shown to be held up in the reticulo-endothelial system, and to cause there an increase of activity which shows itself by various changes in the chemical and physical composition of the circulating blood, including an increase of fibrinogen and blood platelets. This is probably the explanation of the haemostatic action of Congo red, since in most of the cases which did well the coagulation time was abnormally long before the injection, and was reduced to normal by the treatment, the platelet count increasing at the same time. This was particularly the case in haemoptysis from pulmonary tuberculosis, where a prolonged coagulation time appears to be a common finding.

81 Vaccine Treatment of Typhoid Osteo-arthritis

M. LAURENT (*Thèse de Paris*, 1930, No. 266), who records 8 illustrative cases in patients aged from 18 months to 27 years, states that osteo-arthritis, although a rare complication, is always likely to occur in enteric fever, especially in the child. The onset is often insidious and the symptoms ill marked. Timely treatment, however, may diminish such grave complications as dislocation (which is particularly frequent in children) and ankylosis. Vaccine therapy should be applied as early as possible. It is most effective during the onset of the lesions, and may prevent suppuration in a primary serous arthritis. In cases where Widal's test has not been used a polyvalent T A B vaccine should be injected. The doses of the vaccine should be progressively increased so as to produce a general reaction. Laurent states that there is no contra-indication to the vaccine treatment of typhoid osteo-arthritis, and it should be associated with immobilization.

Disease in Childhood

82 Urticaria in Early Infancy

ANNA PINELLI (*La Pediatria*, October 15th, 1930, p. 1134) publishes a synthetic review of recent knowledge in regard to infantile urticaria. The family history of these patients often shows a skin weakness on similar lines, including a sensitiveness to cow's milk or to eggs, and especially to the white of the egg. Various hypotheses have been suggested to explain how these dietetic errors produce urticaria. It may be due to some special susceptibility of the skin, excited by some irritant passing through the nervous or vascular system and setting up congestion, and exudation of serum in the derma. Sometimes the cause is specific, as in the case of cow's milk and eggs or other food; in other cases no food error can be traced. Probably the liver plays an important part in the formation of the substance or substances which set up urticaria. Pinelli describes six main types: urticaria rubra, porcellana (with pale raised blotches), bullosa, pigmentosa, haemorrhagica, and acute circumscribed urticaria chiefly affecting the eyelids. In treatment the usual antipruritic lotions and drugs are mentioned, and stress is laid on the need for caution, particularly in introducing too drastic alterations of diet. Good results sometimes follow desensitization by means of gradually increasing small doses of the incriminated article of food. The administration of peptone, specific or non-specific, has been much recommended.

83 Artificial Feeding in Infants

H. P. WRIGHT and A. K. GEDDES (*Canadian Med. Assoc., Journ.*, October, 1930, p. 537) believe that, since the value of the accessory food factors in infant feeding has been appreciated, the relative unimportance of the actual food factors has been learned, provided always that certain minimum requirements are complied with and that sufficient calories are supplied. In the autumn of 1928 it was decided, at the Montreal Foundling and Baby Hospital, to submit a number of infants to selective feedings—that is, to feed them according to their appetite with the following preparation: lactic acid whole milk 20 oz., and corn syrup (50 per cent.) 2 oz. The results were uniformly successful. The calorie value of each ounce of this milk is between 23 and 24 calories, or slightly higher than that of breast milk; the carbohydrates and proteins are both in greater percentages than in breast milk. All the babies were fed for twenty minutes every four hours (five feedings in the 24 hours). Each infant under the age of 3 months was held while being fed. When any of them began to take 32 oz. of this mixture in the 24 hours, cereals were offered twice daily and vegetable broth once, and the number of feedings were reduced to four. When two platefuls of cereal were taken, the child was as a rule fed only three times a day. Infants 4 months old were usually eating cereal with avidity, and at the age of 6 months were receiving only four feedings in the 24 hours. Boiled water was offered to all infants. Cod-liver oil, rapidly increased to one teaspoonful twice daily, was administered in all cases. Orange juice was also given and quickly augmented to one tablespoonful a day. The authors consider that it is perfectly safe to feed normal babies during the first year with this mixture according to the appetite, and that some such simplified feeding is safer than a scheme which requires modification at regular intervals. Eleven case reports are appended as representative of those of 20 infants who received the feeding described. Only two failed to make satisfactory progress; one of these had congenital syphilis, and the other a cerebral haemorrhage following birth injury.

84 Diagnosis of Pulmonary Tuberculosis in the Infant

G. RUELLE (*Bruxelles-Médical*, October 26th, 1930, p. 1417) bases his diagnosis in suspected pulmonary tuberculosis in infants on the sum of the information obtained from the family history, clinical examination, reaction to tuberculin, and bacteriological and radiological investigations. He remarks that members of the household and near relatives should all be examined; the more intimate the contact the more likely is the infection. Transplacental infection is stated to be quite exceptional. The presence of adenitis, caries of the bone, or gummata indicates the necessity for very careful percussion and auscultation of the lungs. Ruelle holds that a positive Pirquet reaction indicates the presence of living tubercle bacilli in the infant. Since there may be a " silent " incubation period of two or three months, it is necessary to repeat the test, if negative, in suspected cases. If the skin reaction is positive the author advocates injection into guinea-pigs of material swabbed from the throat or antiforminized portions of the stools. Several animals should be inoculated on two to eight occasions, and daily or every other day. The animals are killed after a minimum of thirty days, and only those are considered tuberculous from which reinoculable tubercle bacilli are recovered. Tubercle bacilli may also be found on direct examination of the centrifugalized stomach contents, or, very rarely, the stools. Tracheo-bronchial adenitis, while not necessarily tuberculous, should always be regarded with great suspicion. *X*-ray shadows may be present in the right or left hila; they may be central or may involve the parenchyma of the lungs. Splenopneumonia or Grancher's disease, an acute infection, usually of the left lung, simulating a pleurisy with moderate effusion, is said to give a characteristic diffuse *x*-ray shadow, and to be generally tuberculous in origin. In miliary tuberculosis scattered granular shadows are apparent in the lungs. Cavity formation, not very common, must be confirmed radiologically.

Obstetrics and Gynaecology

85 Tubal Inflation and Salpingography

According to J. NOVÁK (*Zentralbl. f. Gynäk.*, November 29th, 1930, p. 3013) injection of the tubes with lipiodol or similar preparations for radiological purposes is far from being without danger; nevertheless, increasing numbers of foreign patients seeking treatment in Vienna for sterility bring with them radiograms of their Fallopian tubes. Novak describes the post-mortem findings in a patient who died from typhoid fever two months after salpingography, and three weeks after salpingostomy; recent inflammatory disease in the reclosed tubes and in the pelvic peritoneum was present. He cites a case in which, as shown radiographically, the injected oil was still present in the tube after two years. Novak no longer advises salpingography as a preliminary to operative treatment of tubal sterility, and save in very exceptional cases is content with tubal inflation. This is performed shortly after menstruation, but not until gonorrhoea has been excluded by examination of the cervical secretion and/or complement deviation, and (when the adnexa are enlarged) not until there is a normal leucocyte count and erythrocyte sedimentation rate. In none of the author's patients have untoward results followed the use of Rubin's method, and in one case only in which tubal occlusion was demonstrated did pregnancy occur later.

86 Post-operative Obstetric Embolus

J. O. POLAK and V. MAZZOLA (*Amer. Journ. of Obstet. and Gynecol.*, October, 1930, p. 529) discuss the incidence, cause, and prevention of post-operative obstetric embolus. The total incidence of thrombosis and embolism in 12,000 gynaecological and obstetrical cases was found to be 0.5 per cent. The number of cases of thrombosis in the obstetric group was double the number in the gynaecological group. Embolism predominated after gynaecological operations, thrombosis in obstetric deliveries. The authors state that 50 per cent. of all post-operative pulmonary emboli have their source in thrombi of the femoral and iliac veins. All clinical observers admit that pulmonary embolism is more common in pelvic operations, and in women aged 40 or more who are overweight and inactive. Relatively low blood pressure is frequently associated also, and some degree of post-operative infection, however mild. In this series of cases the mortality in gynaecological cases resulting from embolism is nearly twice as great as that resulting from embolism in the obstetric patient. Morbidity was present in 100 per cent. of cases. The conclusions reached by the authors are that venous stasis, the physiological blood changes following operation trauma, and infection are the chief factors which predispose to thrombosis and embolism. As a prophylactic measure they advise a more thorough pre-operative study of the patient, with individual treatment of cases of hypotension, low basal metabolism, leucopenia, anaemia, or hypertension. To increase metabolic activity and improve the circulation of blood in the lower extremities, the employment of passive movements and the administration of thyroid extract before and after operation are advocated.

87 Treatment of the Fibrocystic Ovary

C.-A. CASTAÑO and A. S. INTROZZI (*Gynécol. et Obstét.*, October, 1930, p. 301) in observations at operations have invariably found the fibrocystic ovary to be combined with pelvic varicocele. They believe that alteration in the pelvic sympathetic nerves plays an important part in the etiology of both conditions. In six cases of fibrocystic ovarian disease they have had excellent symptomatic results from ligature and section of all the vascular and nervous elements (the ovarian artery included) lying within the ileo-ovarian (suspensory) ligament near the hilum. The utility of Cotte's resection of the presacral nerve in similar cases is admitted, but the technique of the author's operation is simpler.

Pathology

88 Intradermal Reactions in Early and Late Allergic Syphilis

DUJARDIN and WISER (*Bruxelles-Médical*, August 17th, 1930, p. 1133) consider that the positive reactions to the intradermal inoculation with luetin—a substance obtained by maceration of syphilomata rich in the treponema obtained from rabbits—which occur in certain well-defined cases, have a definite clinical significance, though a positive result in infected subjects is much less general than is the case with tuberculin. A positive reaction is most commonly obtained in tertiary cases, but also in some earlier stages, especially where nervous lesions have followed rapidly on a primary stage insufficiently treated with arsenobenzol. The sequence of events points to the provocation of an early tertiary stage. The same reaction may be obtained in some cases where treatment has been really vigorous, and in certain congenital cases having special sensitivity to the toxins of the treponema. Luetin, according to the authors, thus produces the typical reaction of syphilitic allergy. As already recognized by Noguchi, this allergic reaction is not strictly specific, similar ones being obtainable by the use of various proteins. The present authors suggest that syphilis evolves through non-allergic primary and secondary stages to an allergic tertiary stage which may not be reached for some years, or the disease may remain indefinitely anallergic, the allergic stage being eventually provoked under the influence of treatment, as, for example, by malaria therapy in general paralysis. In a series of 113 cases where the test was tried, negative results were obtained in 23 primary cases (100 per cent.), 14 out of 19 generalized secondary, 7 of 10 localized secondary, 9 of 19 latent cases, and 3 out of 10 tertiary cases where lesions had been present but had been inactive for some years. Severe reactions occurred in three cases where the tertiary manifestations were very recent, and also in another case where a tertiary lesion appeared in the nose three months after infection, exemplifying the highly allergic state of the skin. The authors remark that the occurrence of positive reactions in latent cases is hard to explain; probably tertiary signs may be expected to appear later. They conclude that the development of allergy is promoted by the massive destruction of treponemata, as in recent syphilis when the action of arsenic is as potent as that of fever in general paralysis, and by a maximum concentration of treponemata in the organism, as at the "critical stage" for treatment when the secondary septicaemia occurs, and in general paralysis, where there is frequently a massive concentration of treponemata in the nervous tissues.

89 Streptococci in Infectious (Atrophic) Arthritis and Rheumatic Fever

R. N. NYE and E. A. WAXELBAUM (*Journ. Exper. Med.*, December, 1930, p. 885) have undertaken a series of experiments to determine whether streptococci are frequently present in rheumatic infections. In their first series of cases blood cultures were taken—using the method of Cecil, Nicholls, and Stainsby—from 10 cases of chronic arthritis, 11 cases of acute infectious arthritis, and 12 cases of rheumatic fever; of these, only one culture proved positive, a diphtheroid organism being recovered. Of 35 control cases, 6 positives were obtained, staphylococci, diphtheroids, Gram-positive cocci, and Gram-positive bacilli being recovered. In their second series of cases 5 patients with chronic infectious arthritis and 3 with rheumatic fever were examined, cultures being taken from the blood of seven, the synovial fluid of six, and lymph glands or subcutaneous nodules of four. Altogether positive cultures were obtained from six patients, the organisms recovered being Gram-positive bacilli and diplococci, Gram-negative bacilli, diphtheroids, staphylococci, non-haemolytic streptococci, and *Str. viridans*. In the total series of 41 rheumatic cases *Str. viridans* was obtained only once—from the blood of a patient with chronic infectious arthritis. The diversity of organisms recovered, the fact that duplicate tubes inoculated with the same material were never both positive, and the fact that more positive cultures were obtained from the control than from the experimental series of cases, lead the authors to believe that the positive results were probably due to contamination. The streptococcal origin of rheumatic conditions therefore receives no support from their work.

90 Cholesterinaemia in Diphtheria

J. DONATO (*Thèse de Paris*, 1930, No. 323), who records 44 illustrative cases in children aged from 2 to 14 years, states that while in an ordinary attack of diphtheria the glucose and cholesterin content of the serum is little affected, in severe forms there is a considerable diminution of glycaemia and cholesterinaemia. This diminution appears to have a direct relation to the intensity of the intoxication, so that the estimation of the glucose and cholesterin content of the serum is of value in the diagnosis and prognosis of suprarenal insufficiency, which is the chief cause of malignancy in diphtheria. When recovery ensues, there is always a reaction in the form of hypercholesterinaemia, which appears to be closely connected with the progress of immunization and the formation of antibodies. The administration of total suprarenal extract seems to have a favourable effect on the curve of glycaemia and cholesterinaemia, and consequently on the course of the disease.

The **SPECIFIC OVARIAN HORMONE**
which normally controls and activates the menstrual cycle

SISTOMENSIN
standardised physiologically

dysmenorrhœa, menorrhagia, hæmorrhages of puberty and menopause, hypoplasia of the uterus, disturbances subsequent to menopause or oöphorectomy.

Tablets Ampoules

PROKLIMAN
(Sistomensin Compound)

Association of ovarian hormone with therapeutic agents for the prompt relief of the most pronounced troubles of menopause: cardiovascular and nervous troubles, hot flushes, headache, etc.

Tablets

Hydrosoluble Ovarian Substance

AGOMENSIN

causes hyperæmia of the female genital organs. Stimulates the function of the genital glands and menstruation.

Functional amenorrhœa, oligomenorrhœa, sterility, vomiting during pregnancy, etc.

de KUYPER'S
HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 236 years.

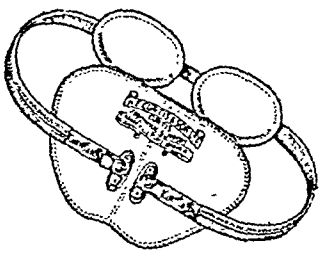
THE CURTIS ABDOMINAL SUPPORT

(Model 1 for average cases. Special designs to meet individual requirements.)



Model No. 1

A scientific support exerting a positive pressure which can be measured accurately. Its range, up to 50 lbs., is far more than adequate for all therapeutic purposes.

Unlike other belts which merely limit distension, the Curtis Support supplies a definite thrust in a backward and upward direction which lifts the fallen viscera into place.

The ideal support for *Visceroptosis* of every degree and variety.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of *Potassii et Sodii Citro-Tartras* and 30% of *Sodii Sulphas* it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably *influencing circulation, glandular secretions, peristalsis, and* metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and *facilitate their* removal.

WHEN YOU PRESCRIBE WARMTH WITH FRESH AIR

All medical men will agree that the practice of heaping thick, stuffy fabrics on the body to keep out the cold is merely increasing the risk of winter chills and influenza. The skin needs ventilation—the impurities in the air round the body must be allowed to escape. Fresh air must have access. Perspiration must be absorbed. That is why Jaeger underwear, made of pure Jaeger wool, is so often recommended as the healthiest underwear for all seasons. All Jaeger underwear is treated against shrinkage. And there are Jaeger Agents in every town.

YOU RECOMMEND JAEGER PURE WOOL UNDERWEAR!

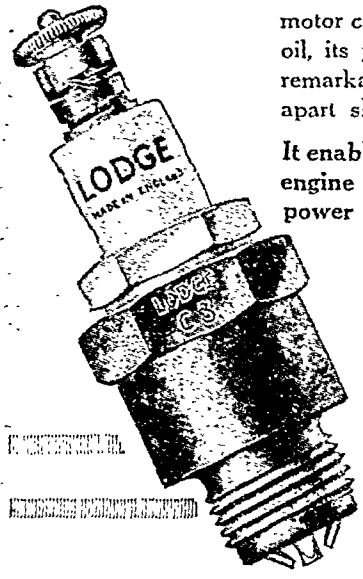
THE
LODGE
SPARKING PLUG

possesses just those qualities that make it the finest plug in the world for all motor cars. It is unaffected by soot or oil, its powers of heat resistance are remarkable, while it can be readily taken apart should cleaning be necessary.

It enables the modern high-efficiency engine to develop its maximum power under all running conditions.



LODGE C3
the plug for nearly all English and Continental engines.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles
5. It is entirely different, unequable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet, giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16. *(Toll Call from London.)*

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in *farming, gardening, and fruit-growing.*

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

County Council of East Sussex.

STEYNING INSTITUTION, near BRIGHTON.

RESIDENT MEDICAL OFFICER AND ASSISTANT ADMINISTRATIVE COUNTY MEDICAL OFFICER (Hospitals).

The County Council invites applications for the above whole-time appointment. The Steyning Institution contains 262 sick beds and 406 other beds, and is under the administrative control of the Master.

In addition to his duties as Resident Medical Officer, the officer appointed will be required to act as an Assistant Administrative County Medical Officer (Hospitals) under the County Medical Officer of Health.

The salary will be at the rate of £600 per annum, rising to £800 per annum by annual increments of £25. The officer appointed will be required to reside in the neighbourhood of the Institution, and will receive a lodging allowance of £150 per annum until a residence is provided.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate may be required to pass a medical examination.

Candidates must be registered Medical Practitioners and must have held resident hospital appointments.

Canvassing in any form will be deemed to be a disqualification.

Forms of application can be obtained from the County Medical Officer of Health, County Hall, Lewes, to whom applications, accompanied by copies of not more than three recent testimonials, must be delivered not later than February 4th.

HUGH J. T. McILVEEN,
Clerk of the County Council.

County Hall,
Lewes.
January 10th, 1931.

County Council of Middlesex.

DISPENSER.

The County Council invite applications for the post of Dispenser at HILLINGDON HOSPITAL, Uxbridge, Middlesex, at a salary of £250 per annum (no bonus).

Candidates must be Graduates in Pharmacy of a recognized University or hold one of the qualifications of the Pharmaceutical Societies of Great Britain. The officer appointed must be acquainted with the running of the pharmaceutical department of a modern hospital, and ability to undertake simple biochemical and microscopical investigations will be additional qualifications.

The officer appointed will be required to devote whole time to the duties of the post, to contribute to the County Council's Superannuation Fund, and for the latter purpose will be required to pass such medical examination as the County Council may direct.

The appointment is terminable by one month's notice on either side.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than February 7th.

No special application forms are provided.

Envelopes must be endorsed "Dispenser."

Canvassing, directly or indirectly, will be a disqualification.

ERNEST S. W. HART,
Clerk of the
County Council.

All communications to be addressed to the Branch Manager, BRITISH MEDICAL BUREAU, 33, CROSS ST., MANCHESTER.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1782 (1783)

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

PREDIGESTED MILK
(25% Protein Conversion)

PREDIGESTED WHEAT
(25% Starch Conversion)

Powdered by the
COW & GATE
Improved
Roller Process

Peptalac REGD.

THE NEW INSTANT PREDIGESTED FOOD

Predigestion of *starch and milk is guaranteed and is effected under the most* exact scientific conditions in our laboratories before powdering. This means that when required for use it can be immediately and simply prepared by the *mere* addition of hot water. The C. & G. Improved Roller Process is used ensuring retention of the full mineral and vitamin content with freedom from pathogenic organisms.

PEPTALAC is indicated in all those cases where the powers of the digestive tract are insufficient to deal with that amount of food necessary for maintaining health—for nursing mothers with weak digestions, in ante- and post-operative surgical cases, in achlorhydria, peptic ulceration, cancer of the alimentary tract, in all forms of convalescence and in old age.

MALARIAL NEPHRITIS

By GEORGE GIGLIOLI, M.D., D.T.M. & H., Chief Medical Officer to the Demerara Bauxite Co., British Guiana. 17 Illus. 8s. 6d. Post. 4d.

A CHEMICAL DICTIONARY

By INGO W. D. HACKH, San Francisco. 232 Illustrations. Over 100 Tables. 42s. Post. 1s.

THE EMPIRE SERIES

"This addition to Churchill's 'Empire Series of Textbooks' will be cordially welcomed by practitioners who desire a good handbook of treatment of tropical diseases. It is an admirably arranged, thoroughly practical, and well-written book, in which a praiseworthily large part of the text is devoted to the discussion of treatment. In it is incorporated the most recent literature on tropical medicine. The authors are to be congratulated on an achievement which comes as a real boon to those who have long wished for a simple and, at the same time, authoritative and reliable textbook on the treatment of tropical diseases."—Jl. MED. ASSOC. S. AFRICA.

TROPICAL MEDICINE

By Sir LEONARD ROGERS, C.I.E., M.D., F.R.C.P., F.R.C.S., F.R.S., and Maj.-Gen. JOHN W. D. MEGAW, I.M.S., C.I.E., V.H.S., M.B. 1 Coloured Plate, 77 text-figures. 14s. Post. 9d.

PUBLIC HEALTH PRACTICE IN THE TROPICS

By J. BALFOUR KIRK, M.B., D.P.H., D.T.M. & H., Director, Medical and Health Department, Mauritius. 80 Illustrations. 15s.

SURGERY IN THE TROPICS

THE 'ALLENBURYS' CASTOR OIL

Is Tasteless and is the Standard of Quality

Supplied in bottles at 8d., 1/3, 2/3 and 4/- each

Vapo-Cresolene Est. 1879
Sold by Chemists
Write for descriptive Booklet No. 29.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

BAILLIÈRE, TINDALL & COX

What Will Physical Therapy Mean To My Practice?

THOUSANDS of physicians are still pondering over this question. They are aware of an increasing number of articles on physical therapy in their medical journals, but have not found time to make a real survey or summary of the literature.

"Physical therapy," to quote the Council on Physical Therapy of the American Medical Association, "must be recognized as a definite part of medicine to be practiced and controlled by graduate physicians. It should be used only as one of the triad of medicine, surgery and physical therapy."

For the convenience of the general practitioner and specialist alike, we have prepared the above illustrated booklets of abstracts and digests from recent literature on Physical therapy. They give the gist of articles by many authorities—a key to this literature as it pertains to your practice. We believe this abstract service to be an ethical means of furthering your interest in the subject.

Your request on the above coupon will receive prompt attention.

Fill out below and mail:

MICKLEFIELD IRRADIATED MILK

TREATING THE COW

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 " " Micklefield " " "

(1) Average increase in height .605-in. (2) Average increase in weight 9.72 ozs. more than (1).
(2) " " " .610-in. (3) " " " 10.9 ozs. more than (1).
(3) " " " .744-in.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every week-day in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

Rover offer a range for general and special service

The Light Twenty Coachbuilt Saloon

ALL Rover cars are eminently suited to the heavy duty list of the Doctor. Where economy of running and maintenance has to be a first consideration the Rover Family Ten from £189 claims the attention, with its proved record of economy and its known efficiency in performance. For those who prefer a larger car the Two Litre is a six-cylinder model of 16 h.p., is fast, flexible, low to the road and a delightful car to handle. The Light Twenty and Meteor have six-cylinder engines of 19.3 h.p. The differences lie in carriage accommodation and preference rests on individual needs. There is also for Town work a very handsome limousine at a most reasonable price.

Ask your Dealer to show you the car that interests you.

A palatable combination of Lactose & Dextrin
for changing the intestinal flora

Lactose 73%, dextrin 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora. Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora. An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced—Lacto-Dextrin being highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon. In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination.

PSYLLA

. . . an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of BATTLE CREEK Psylla (Plantago Psyllium) is invaluable as an accessory. The small brown seed when in contact with water swells into a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Gt. Tower St., London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

HORLICK'S MALTED MILK has been tested by the Medical Profession for close upon half a century, and to-day is as confidently prescribed as at any time in its history. Whenever it is necessary to build up a patient—after acute illnesses, in neurasthenia, in tuberculosis or other debilitating conditions—HORLICK'S satisfies the clinical requirements. A combination of milk and the soluble extracts of malted barley and wheat, it forms a partially predigested, easily assimilated diet, which places no strain on the weakened digestive powers of the patient. Protein and "protein sparers" are present in well-balanced proportions, and metabolic needs are satisfied in the most economical manner: body tissue is spared and re-building is accomplished to the satisfaction of doctor and patient. Should the needs of the patient appear to demand it, HORLICK'S can always be "fortified" by mixing with milk, or by forming an emulsion with olive oil or cream.

'CAPROKOL'

Brand of Hexyl-Resorcinol

The urinary antiseptic characterised by the following attributes:—

1 Powerful germicidal effect in urine of any reaction

2 Analgesic action upon the urinary mucosa

EVANS SONS LESCHER & WEBB Ltd.
56, Hanover Street, LIVERPOOL
and LONDON

THROAT THERAPY.

Evans' Pastilles are prepared to a formula of the Liverpool Throat Hospital. Their action is soothing and demulcent, the formula being carefully balanced with both these objects in view. Evans' Pastilles relieve harshness and irritation and maintain their effect for some time after the pastille has dissolved.

Sold in 1/- tins or in bulk for dispensing.

A physician's sample will be gladly sent on request.

The Medical Profession
when prescribing
"Liquor Carbonis Detergens"
SHOULD ADD THE WORD
Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

Reaching Laryngeal and Bronchial Inflammations

MANY laryngologists are advising the treatment of laryngeal, tracheal and bronchial inflammations by the direct route, nebulized spray solutions—in addition to the use of oral medication.

Mistol is ideally suited to this form of administration. When used in a nebulizer, it forms an exceedingly fine, almost invisible, vapour. This spray is unirritating to the upper respiratory passages and is drawn into the larynx and bronchi with each inspiration. In this way it reaches and exerts its therapeutic action upon the upper respiratory passages.

The ingredients of Mistol—menthol, camphor, eucalyptol, and chlorbutol in high-grade liquid paraffin—are endorsed by all leading rhino-laryngologists.

They relieve congestion and hyperemia in inflamed mucous membranes, diminish abnormal secretions, and aid in the return to normal conditions.

More and more physicians are finding in Mistol administered by means of a nebulizer a valuable ally to oral medication for laryngeal, tracheal, and bronchial inflammations.

Mistol

REG. TRADE MARK

MADE BY THE MAKERS OF NUJOL

Nujol Laboratories:

128 Albert Street, Camden Town, N.W.1.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective laxative.

Manufactured in London for the past 100 years.

DINNEFORD & CO. LTD.

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7

Works: KING'S LANGLEY, HERTFORDSHIRE.

M233

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

Alasil

M 235

ARTERIO-SCLEROSIS

IT is an old adage that a man is "as old as his arteries," meaning that degenerative changes in the arteries are largely responsible for senility.

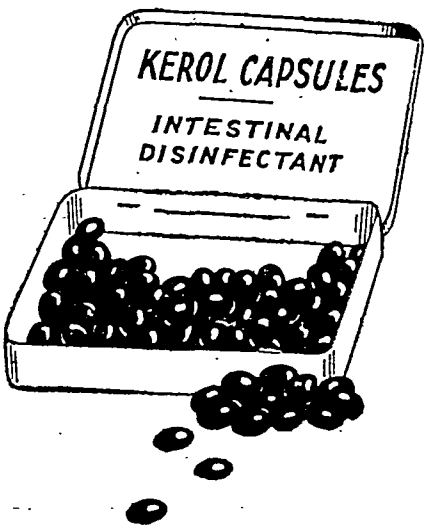
The modern view is that arterio-sclerosis is produced by increased blood-pressure, and that increased blood-pressure results from the absorption of "pressor" substances developed by putrefactive bacteria in the intestine.

(Prof. A Robin, among his suggestions for the treatment of arterio-sclerosis, emphasises in the first place the need to remove the alimentary toxic factors which are causative of arterial hypertension.—*Therapeutique Usella du Practicien*, p. 344.)

To retard the activity of the putrefactive bacteria, Metchnikoff introduced the soured milk treatment; but how much better it is to use an antiseptic substance. The ordinary so-called intestinal antiseptics, such as Salol, possess little real disinfectant power, and more potent germicides, such as Phenol, are absorbed, and, in sufficient dose, are toxic.

The active principle of Kerol, besides being a very potent germicide, is not absorbed, and is therefore non-toxic. The rational treatment of arterio-sclerosis would, therefore, include adequate intestinal disinfection by means of the keratin-coated Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated): they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.



Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

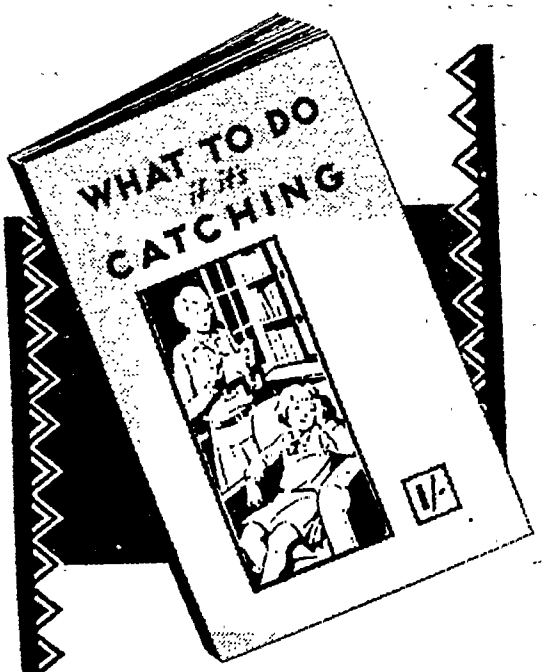
Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

Eases the work of Doctor and Nurse



A compendium of information written in simple language giving the public directions for preventing the spread of infectious illness in the house and in the district.

Compiled and published in co-operation with eminent medical and health authorities by Newton, Chambers & Co. Ltd., proprietors of Izal, the disinfectant most used by public health authorities throughout the world.

Now being widely advertised in the daily press.

Private circulation among Doctors has brought many appreciative letters of which the following are typical.

"'What to do if it's catching.' The information it contains is of the greatest value; and I should like to see it in the hands of all parents; it would prove a most useful guide to them . . . ."

M.B., B.S. (Lond.), F.R.S.I., D.P.H.
Medical Officer of Health.

"[illegible] information and advice when confronted with the various illnesses and emergencies which form the subject-matter of this valuable booklet."

M.D., Ch.B. Hons., D.P.H.,
County Medical Officer.

"What to do if it's Catching" saves the doctor endless explanations and can be recommended with complete confidence.

CONTENTS INCLUDE:

- How illness spreads.
- Rules for semi-isolation of invalid.
- Rules for complete isolation.
- Cleaning up the sick room.
- What the law says regarding infectious diseases.
- First aid in the home.
- All-the-year round health precautions.
- Rules for personal hygiene.
- What to do in sudden emergencies before the doctor comes.
- Directions for family emergency chest.
- Household hints.

the disinfectant most used by public health authorities throughout the world. Z m 88

MEASLES
and
WHOOPING COUGH

The danger of these disorders is often in their far-reaching secondary effects.

During Convalescence from Measles there is a very special liability to tuberculosis invasion, many victims subsequently succumbing to Tuberculosis, Broncho-Pneumonia or Surgical Tuberculosis, and there is the same liability to Broncho-Pneumonia from Whooping Cough.

Virol is composed of Bone Marrow, Glycerine Extract of Red Bone Marrow, Malt Extract, Eggs, Lemon Syrup and Salts of Lime and Iron.

The Vitamins are present in Virol in its manufactured state.

Phagocytosis

The raising of the patient's powers of resistance is therefore important. Virol has been proved to increase the phagocytosic action of the leucocytes against the germs of Tuberculosis.

The convalescent stage calls for special reparative nutrition. Virol has a marked effect upon the conservation of the tissues, repairing the waste and restoring the equilibrium of a healthy metabolism.

VIROL

More than 3,000 Hospitals, Sanatoria, and Infant Clinics use Virol regularly.

A Liver Preparation your Patients will enjoy

'Byno' Hepol Registered.

Trade Mark

For Pernicious Anæmia and Sprue

'Byno' Hepol is a solution of Liver Extract 'A. & H.' in 'Bynin' Liquid Malt.

Supplied in 4 oz. and 10 oz. bottles

The presence of the malt extract assists the digestion and assimilation of the liver which renders its continued use less prone to produce nausea.

Three tablespoonfuls of 'Byno' Hepol are equivalent to eight ounces of fresh mammalian liver, the amount usually ordered to be taken daily in the treatment of pernicious anæmia.

Remarks
ON
SOME FORMS OF SPASM IN CHILDHOOD: THEIR CAUSE AND TREATMENT*

BY
A. DINGWALL FORDYCE, M.D., F.R.C.P.ED.
HONORARY PHYSICIAN, ROYAL LIVERPOOL CHILDREN'S HOSPITAL

It has been said[1] that "a child is the sum total of his movements or tendencies to move." Movement follows on muscular contraction resulting from nervous stimulation, and spasm in ordinary medical parlance is a term used to mean involuntary sustained muscular contraction occurring as an abnormal manifestation. Such spasm may be usefully considered as it discloses itself to the clinician at different sites and in different bodily conditions.

An abnormal condition of neuro-muscular apparatus—for example, spasm—may be produced by a local peripheral cause, or result from a primary lesion or abnormality of the central nervous system interfering with its function of nervous control. It is not possible, however, to dissociate the mental functions and the functions of nervous control in the central nervous system, and spasm may occur from disturbance of the mental functions, with no detectable abnormality in local neuro-muscular apparatus or in the central seat of nervous control. Thus emotional disturbance may be the primary exciting cause. Careful attention must also be given to the degree of development of the intellectual powers in childhood. If, then, we have to take into account such varying factors in etiology, we must go further and consider important influences affecting the functions of the central nervous system. Such, in this connexion, are the influence on bodily processes of endocrine secretion, calcium metabolism, and the phenomena of anaphylaxis; the results of training and education; and the development of inhibition.

The symptom of spasm may be considered in four groups.

1. Congenital in origin, associated with local organic change in infancy, and with no detectable lesion of the nervous system.
2. The result of gross intracranial abnormality or lesion, congenital or acquired.
3. A symptom of disease resulting from vitamin deficiency in infancy.
4. A symptom dependent on nervous hyperexcitability, congenital or acquired, temporary or permanent.

Consideration here will be restricted to some conditions in Group 4. While these occur largely in "nervous" children, there is an interesting aspect of abnormal nervous excitability which is capable of practical demonstration—namely, the phenomenon of facial irritability.

CHVOSTEK'S SIGN

It has long been well known that a positive Chvostek's sign (facial irritability) is no uncommon phenomenon among children of school age, both healthy and debilitated. Eckert[2] investigated the frequency of its occurrence in 13,854 Austrian children and found it present in (1) 22.8 per cent. of boys and 20.1 per cent. of girls in Vienna; (2) 7.1 per cent. of boys and 7.8 per cent. of girls in provincial cities; and (3) in an intermediate percentage in the country districts. Various observers[3, 4] in this country have also found that it is by no means rare, but its significance in children of school age is disputed. As a result of the examination of a consecutive series of 400 children between the ages of 6 and 14 I found it present in twenty-eight, or 7 per cent.

It is impossible to believe that the sign has no significance. In spite of its obscurity, there seems to be a type of child in which its presence points to certain tendencies in reaction to a specific treatment. For some considerable time I have given to practically all asthmatic children, after treatment in the ward, a prolonged course of treatment by ephedrine supervised in the out-patient department. This has usually had good results, and never untoward ones, except in five cases in which it was stated that the children suffered some "collapse," lethargy, tendency to faint, shortly after taking the medicine. In these five cases F.I. was marked, and in only two, in which F.I. was negative, have symptoms of a minor degree occurred. This will be referred to later when discussing asthma; at present it is sufficient to say that the reaction appears to depend upon the degree of alteration in systolic blood pressure brought about by the administration of a particular internal secretion in a child of unstable nervous constitution.

BLOOD CALCIUM CONTENT IN SPASMODIC CONDITIONS

The presence or absence of the sign frequently varies much from time to time in the same child, but it is often present with a normal blood calcium content. In cases of tetany in infants it has been shown[5] that the calcium in the blood serum is greatly reduced. Italian investigators have found that a solution of calcium when applied to the brain diminishes its irritability to electrical stimulation,[6] while the peripheral nerves are even more sensitive to lack of calcium than the central nervous system.[7] It is interesting, therefore, to consider if variations in the bodily content of calcium bear any relation to different spasmodic conditions.

In infantile spasmophilia the total calcium in the blood is low, but it is because the ionic calcium is low that nervous symptoms occur. In other forms of tetany there may be no diminution of calcium in the blood serum, but the existence of an alkalosis, and in these cases the chlorine, not the calcium, is the important factor in treatment by calcium chloride. The place of calcium in the etiology and therapeusis of symptoms has then to be considered along with other factors, none more important than those associated with the endocrine system, particularly the parathyroids—and with vitamins, particularly vitamins A and D.

The significance of the parathyroids in the production of tetany in young children is still uncertain, but it is unusual for the parathyroid gland to be the primary cause of the trouble.

The conditions which produce rickets and spasmophilia are those in which there is a lack of the fat-soluble vitamins A and D. Deficiency of these vitamins causes lack of absorption of calcium, an abnormally low blood content of ionic calcium, and spasmophilia in infants. The blood content of ionic calcium can be raised either by increasing absorption, this being the fundamental method, by administration of vitamin (by irradiation, cod-liver oil, irradiated ergosterol); or by hypodermic administration of Collip's parathormone, altering and utilizing calcium reserves in the body, especially the calcium in the bones. The latter is obviously almost always an undesirable method of attempting to raise blood calcium in young children.

Apart from infantile spasmophilia there appears to be no definite relationship between blood calcium content and spasmodic conditions, or a positive facial irritability. Thus in fifty consecutive examinations of blood calcium, taken in seventeen cases of chorea under treatment, I have obtained reports varying from 7.33 mg. to 13.5 mg.

* Abstract of paper read before the Wallasey Medical Society on December 10th, 1930.

per 100 c.cm., the severity of symptoms bearing no relation to the blood calcium content. In asthma and various neuroses the figure varied from 7.0 mg. to 12.3 mg.

Equally difficult to estimate is the value of treatment directed towards increasing blood calcium. It may be said, however, that where blood calcium is approximately normal in amount—that is, from 9 to 11 mg. per 100 c.cm.—no benefit is to be expected from any form of such treatment; when blood calcium is low, the all-important measure in therapeusis is administration of vitamin D (ostelin, for example). Granted that the child is under satisfactory conditions, dietetic and hygienic, the administration of calcium chloride or of parathormone may or may not cause improvement where there is low blood calcium; with the addition of vitamin D the prospect of improvement is great. Parathormone alone may cause a marked rise, but, as already noted, there are drawbacks to employing this treatment in childhood, and vitamin D is a safer and more powerful agent.

RELATION OF THE ENDOCRINE SYSTEM TO SPASM

The relation of the endocrine system to the autonomic nervous system is very close and complicated. According to Eppinger and Hess[8] two types of individual can be distinguished in whom the normal balance of the sympathetic and parasympathetic divisions is disturbed—namely, a group displaying undue irritability of the sympathetic (sympathicotonia), and another group with undue irritability of the parasympathetic (vagotonia). In this latter group are subjects liable to anaphylactic conditions—asthma and certain skin conditions—and diminution or removal of symptoms in these cases is to be obtained by stimulation of the sympathetic. If, then, allergic individuals are vagotonic, remedies having this effect are likely to be beneficial.

The ductless glands, which act in closest association with the autonomic nervous system, are the suprarenals, thyroid, and pituitary. While the function of the suprarenal in health is very uncertain, the effect of stimulation in times of stress through the outpouring of medullary secretion or adrenaline results in stimulation of the sympathetic and of thyroid activity; the converse is also true. Both diminish undue symptoms of vagotonia. For our present purpose it is important to note that suprarenal activity depresses the broncho-constrictors and that the characters of reaction to the therapeutic administration of adrenaline differ considerably in different individuals.

Thyroid instability is very marked in childhood. When thyroid activity is strained or excessive, all metabolic processes are increased in rate, and response to all forms of physical and mental stimulation is exaggerated. This may occur with the onset of puberty, infection, digestive or other metabolic disorder, or as a result of emotional strain; one outstanding characteristic of resultant excessive thyroid activity is great emotional excitement.

Even minor degrees of endocrine disorder, however, may cause mental disturbance—intellectual and temperamental. Cerebral organization is primarily stimulated by sensory impressions, and all of these are associated with some degree of emotional activity. "But our sensory reactions are more true to type, more constant in relation to the objects and impressions that excite them, than are our emotional reactions."[9]

EMOTION AND INSTINCT

Emotion is not only a mental, but also a bodily process; every kind of emotion is normally accompanied by widespread physical changes, and excessive emotion may produce various forms of physical stress, disorder, or actual disease. Further, emotion not only has a sensory, but also a cognitive quality, from which chiefly arises the possibility and the danger of the artificial production of emotion. Healthy emotion may be regarded "as a mode of experience which accompanies the working within us of instinctive impulses," and healthy emotion has as an essential feature an impulse to action. We have the outstanding example of fear with the suprarenal preparation for flight. Excessive emotional excitement may cause physical strain or disease, which again may increase susceptibility to emotional reaction, or, on the other hand, physical disorder may in the first place lead to hyperemotional conditions. In this connexion digestive disorder, whether as a primary condition or secondary to infection and fever, is especially noteworthy.

Allusion has already been made to the relationship between emotion and instinct. While the dominating parental instinct is the "mother of both Intellect and Morality," its unwise expression may ruin the child mentally, morally, and physically. The human young require prolonged tutelage, a guarded lengthy youth wherein slow development and organization may occur. During youth experience should be gained by free activity without full responsibility. If instincts are unduly curbed, if inhibitions are prematurely developed, trouble is inevitable. If a natural, healthy, slow, emotional development is gainsaid, thwarted reactions and activities disclose themselves in abnormal forms or degree of emotion, general disorder, and often in forms of neuromuscular disturbance—spasm.

We may say, therefore, that consideration of many spasmodic conditions in childhood involves study of general mental and physical conditions, and that the result of such study along the lines indicated by the spasm present is likely to give important indications for both general prophylactic and therapeutic measures.

ASTHMA

The asthmatic is vagotonic, and consequently sympathetic excitors are likely to prove useful in treatment. Following on the subcutaneous use and proved value of adrenaline in the acute condition came the reintroduction of ephedrine, efficacious by the mouth. Both these agents depress the broncho-constrictors, cause vaso-constriction in the bronchial mucous membrane, have a pressor action on the circulation, and raise blood sugar. Ephedrine is best given on an empty stomach; the effect takes some thirty minutes to occur, and lasts about five hours. It has been reported that some persons fail to respond to ephedrine, that in some tolerance is produced, while in others serious collapse may follow.

During recent years I have employed very largely in treatment peptone injections followed by ephedrine administration and as long supervision as possible. In the course of such treatment in approximately fifty cases certain points of interest have arisen, the cases being those in which gross disease of the chest was excluded by *x* rays, diet adjusted when opportunity permitted, and focal sepsis attended to. The series was restricted to hospital patients, and while in most of them protein cutaneous tests were made, in none were the results of practical value. In many instances multiple positive reaction occurred for which the most desirable treatment appeared to be general rather than specific. It is not true, however, that skin tests in early childhood are valueless, for in several other asthmatic patients, whose cases are not here included, dramatic benefit followed on treatment suggested by positive skin reactions.

A positive Chvostek's sign is not rare in asthmatic children, most of whom are negative to this test, which, whether positive or negative, is no sign of the blood calcium content. Many cases of asthma with F.I. apparently consistently negative improve greatly under treatment by peptone and ephedrine. Some, on the other

hand, show no marked improvement, but in none does ephedrine cause serious "collapse." One of the effects of adrenaline or ephedrine administration is a rise in the blood pressure, and it is a common experience in cases which respond to ephedrine to find that from half an hour after its administration the systolic pressure is distinctly raised for some hours. There are, of course, many difficulties and fallacies associated with accurate blood pressure estimations, but, granted the confidence and ease of the child, these are not insuperable so far as general approximations are concerned.[10] In the cases of the type which I have mentioned the average response in a child of about 8 to 13 years of age to 1/2 grain of ephedrine is a rise in systolic blood pressure of rather less than 20 mm. of mercury, the diastolic pressure remaining stationary. In cases which do not respond clinically to treatment by ephedrine, and whose F.I. is persistently negative, it may be found that there is no blood pressure response to the drug, and that even when its administration is reinforced by thyroid there is still no response, or almost none.

Other children suffering from asthma have a variable F.I. reaction and respond indifferently to ephedrine—that is, they have an occasional attack of asthma while taking the drug. They have little or no blood pressure reaction, and they suffer no "collapse."

Lastly, there are some children who, a short time after taking ephedrine, suffer from "collapse," weakness, dizziness. I have met with 7 such cases—5 severe and 2 slight. In all the cases in which the collapse was severe, marked F.I. was present; in the mild cases it was absent. In all 7 cases the rise in systolic blood pressure was very marked after administration of ephedrine, the diastolic pressure remaining approximately level. In one case over several estimations the average rise was 26 mm. Hg, in another 30 mm. Hg, and in a third 40 mm. Hg. Symptoms can usually be avoided by smaller dosage. As a part of prophylactic treatment the prolonged administration of ephedrine is usually beneficial and always safe. It is most usefully given thrice daily before meals in a dosage of approximately 1/4 grain to a child aged 5 years and 1/2 grain to a child aged 10 years. When combined with careful and prolonged supervision—the most important element in treatment—the prognosis is good in early uncomplicated cases.

CHOREA

Chorea is a symptom, not a disease. When we consider the various conditions occurring at the different periods of life with which chorea may be associated, we find that all "have this in common, that the victim is not in possession of fully developed mental powers."[11]

Chorea occurs in the young; it may result from the existence of intracranial lesions; or it may owe its origin to constitutional nervous instability. In all cases its onset is determined mainly by the emotional side of mentality. In childhood the chief importance of the symptom lies in the fact that it is usually associated with rheumatic infection. At this period of life some degree of nervous instability is natural. For the proper development of emotional control suitable experience is necessary. Lack of, or abnormality in, education and training may lead to emotional disorder, and may also form the basis of faulty motor control.

In the treatment of chorea many drugs have been tried, vaunted, and discarded. Notice is taken here of only two methods of treatment: the one directed to alteration of calcium metabolism and the other to nervous control by means of nirvanol.

My experience in regard to rheumatic chorea is that diminution in the amount of blood calcium cannot be an important factor in determining the symptom. In fifty recent examinations the reports revealed that in twenty-one cases the blood calcium was between 9 mg. and 11 mg. per 100 c.cm.—that is to say, within the limits of the normal; in twenty-one instances it was below normal, and in eight above normal.

If, as was the case, very severe and acute chorea occurs with blood calcium figures above normal, the possibility that lack of blood calcium is an essential element in the development of the symptom is excluded. My evidence further goes to show that methods directed towards increasing ionic calcium have no marked influence on the symptom, and that they do not, in fact, in many cases increase the blood calcium content.

The methods used have been oral administration of calcium chloride and ostelin, and hypodermic injection of parathormone with ostelin by the mouth. On the latter treatment the blood calcium of a boy, aged 9 years, rose from 7.2 mg. to 11 mg. per 100 c.cm. in the course of three weeks, but the chorea remained very severe. In another case treated with parathormone, calcium chloride, and ostelin, the blood calcium figure during a period of six weeks was between 9 mg. and 9.3 mg. per 100 c.cm., and yet the child steadily improved.

A long-recognized method of treating choreic children has been by means of nerve sedatives. Of drugs recently introduced, nirvanol was found very useful in Germany for the treatment of various adult conditions, and it has later been largely employed for the treatment of chorea in childhood. It appears that in order to have any beneficial effect this drug, which is closely allied to luminal, has to be given in dosage sufficient to produce a somewhat violent reaction—"nirvanol sickness"—and that excessive dosage is dangerous.

In a series of ten consecutive cases of chorea treated with nirvanol, there was a good result in five. Although improvement was speedy and without distressing symptoms, it was accompanied by rash, pyrexia, and some initial exacerbation of symptoms. Persistence of improvement, however, was no more marked than with various other methods of treatment. In two of the other five cases great exaggeration of symptoms called for cessation of treatment. In one case hyperpyrexia with glandular enlargement was followed by rapid improvement; in the two others improvement was slow, and the ultimate results unsatisfactory. While nirvanol is sometimes associated with very satisfactory results, its use is severely restricted by the reaction it evokes, which is not entirely without danger.

FITS

The symptom of epilepsy occurs in various forms in childhood other than those of typical grand or petit mal, or of Jacksonian epilepsy. Early diagnosis is often difficult. A commencing idiopathic epilepsy may show itself for a long time solely by recurrent attacks of visceral spasm, and it may be only with the advent of an obvious fit, when the condition is fully established, that anti-epileptic treatment is begun.

Three common causes of fits due to gross intracranial abnormality are birth trauma, infantile cerebral paralysis, and amentia—for example, syphilitic meningitis. Epileptiform attacks may also occur unassociated with any gross intracranial abnormality as a symptom of, or in conjunction with, simple primary amentia, or they may be of the nature of idiopathic epilepsy. Since an ament is prone to fits, it is fundamental for prognosis to recognize whether amentia is present or not.

In a recent review of 129 children of school age noted as being sufferers from "epilepsy" I found that in 35 there was evidence of an organic cause or of primary

amentia; that in 16 out of the 94 cases of idiopathic epilepsy the patients were imbeciles, while 16 out of the 35 cases of organic lesion of the brain or primary amentia were imbecile. When a child has neither gross organic abnormality nor primary amentia but takes fits, these may have very different etiology and prognosis, and call for very different treatment. Epileptiform attacks forming part of the picture of spasmophilia—Group 3—are associated with rickets; they are intimately connected with the metabolism of calcium and phosphorus, are controlled by calcium injection, and can be prevented and cured by means of vitamin D. The ultimate prognosis here, for the mental condition also, is good.

Fits that may be classified under Group 4 are of certain types—for example, (*a*) infantile eclampsia, (*b*) an occasional fit or fits, (*c*) pyknolepsy, and (*d*) characteristic idiopathic epilepsy. In all, the presence or absence of an essential or idiopathic epilepsy may be conjectural for a time, but in none may the matter be lightly regarded. Although we have definite signs in spasmophilia for an independent diagnosis, and a definite exciting cause, the importance of a possible underlying diathetic trend towards convulsion is even here hard to evaluate.

When dealing with cases of infantile eclampsia we are on even less sure ground. Under this term I include the type of convulsions occurring during the first few weeks of life, usually in boys, where there is no apparent cause and often no digestive disorder, where the fits are of the nature of short general convulsions repeated at brief intervals, where other treatment is unavailing, but where temporary chloralization produces a permanent cure. Whether or not we have here to deal with an anaphylactic phenomenon is not known.

With a child who has an occasional fit we cannot altogether dismiss the possibility of an underlying vice of nature, provided there is no obvious cause, such, for example, as alkalosis. There is no certain test. But family and personal history, precedent or accompanying symptoms, the general physical and mental condition, may all go far to confirm a diagnosis in one or other direction.

In the rare type of case described as pyknolepsy we find that a previously healthy child of about 4 or 5 years of age suddenly begins to have fits of the nature of mild petit mal, which occur very regularly and usually very frequently from the onset. There may be as many as a hundred daily. As they commence, so they continue. No treatment has any beneficial effect; clinically striking is the fact that in spite of long-continued frequent attacks there is no mental impairment and no physical ill-health. After a variable number of months or years the attacks cease as suddenly as they began.

In striking contrast to such a course are most cases of ordinary idiopathic epilepsy; here the treatment consists essentially in attempts to restore nervous tone, and this demands attention to all bodily functions, particularly digestion and excretion. Chloralization is not successful, but the regular and long-continued administration of bromide and probably luminal is of the utmost importance. It is also necessary to establish intelligent control of instinct and emotions, to develop good habits, and to inculcate obedience, reticence, and modesty. Careful guidance of interest, occupation, and scholastic instruction is helpful. In some cases many of the peculiarities of the epileptic are due rather to his training, or rather spoiling, than to his weakness itself. The child is commonly not only a victim of a neuropathic heredity, but suffers also from a psychopathic home environment. Loose control is highly deleterious: the more average-normal his training the better. The satisfactory care of chronic nervous or spasmodic conditions, especially of chorea, asthma, and epilepsy, demands the co-operation of parents, nurses, teachers, and doctors, and continuity of treatment for a long time.

SUBPHRENIC ABSCESS

BY

W. D. DOHERTY, M.Ch., F.R.C.S.

SENIOR SURGICAL REGISTRAR AND TUTOR, GUY'S HOSPITAL, AND SURGEON, HAMPSTEAD HOSPITAL FOR CHILDREN

AND

R. P. ROWLANDS, M.S., F.R.C.S.

SURGEON, GUY'S HOSPITAL

A subphrenic, or subdiaphragmatic, abscess is a limited collection of pus just below the diaphragm. Frequently gas, either from a perforated viscus or as a product of gas-forming bacteria, is also present in the abscess cavity.

H. L. Barnard,[1] in his excellent paper upon this subject, analysed seventy-six consecutive cases, and classified subphrenic abscesses as follows:—

Intraperitoneal: right anterior, right posterior, left anterior, left posterior; of these, anterior abscesses are more common than posterior, especially on the left side.
Extraperitoneal: right, left; of these, the right-sided is much more frequent.

The falciform ligament is the dividing line between the right and left intraperitoneal abscesses, and the lateral ligaments of the liver separate the anterior from the posterior varieties. The right extraperitoneal space under the diaphragm is small, and is limited by the coronary ligament of the liver; the left extraperitoneal space is near the upper pole of the kidney. Extraperitoneal abscesses, however, may travel upwards behind the peritoneum from the colon, appendix, or kidney, pushing the peritoneum forward and eventually occupying the large space under the diaphragm. Sometimes a subphrenic abscess extends downwards into the subhepatic space on either side of the middle line. In the present series of 49 cases, 36 occurred on the right side, and 13 on the left.

CAUSES

Micro-organisms may travel by the blood stream from any part of the body and cause a subphrenic abscess, but the abdominal viscera are naturally the sources of most abscesses in this position, and of these the stomach and the appendix originate the large majority. The liver, gall-bladder, and bile ducts together contribute the next largest group of cases. Here the infection is usually spread direct from a perforated viscus, but it may be carried by the portal veins or by the lymphatics. Diseases of the chest, especially of the lungs, cause a few subphrenic abscesses; diseases and injuries of the chest wall, particularly of the ribs, are also etiological factors in a few cases. Either systemic or portal pyaemia may give rise to a subphrenic abscess. Many different organisms have been found in these abscesses, notably the *Staphylococcus aureus*, streptococcus, pneumococcus, *B. coli communis*, *B. pyocyaneus*, and *B. typhosus*. Subphrenic abscesses are most frequent between the ages of 20 and 50, and they are distinctly commoner in men than in women.

An analysis of 49 consecutive cases at Guy's Hospital shows the following causes:

Perforated gastric and duodenal ulcers*	20
Acute appendicitis	12
Blood-borne	6
Acute cholecystitis	4
Carcinoma of colon	3
Carcinoma of stomach	3

* This includes subphrenic abscesses found post mortem as part of a general peritonitis.

SYMPTOMS

Fever, remittent or intermittent, and with or without rigors and associated abnormal physical signs at the base of the chest, suggest a subdiaphragmatic abscess, especially if there is a known source of infection such as a recent appendicitis or perforation of a gastric or duodenal ulcer. Dullness over the lower part of the chest is the most constant local sign, and the upper limit of this is often dome-shaped. This dullness is continuous with that of the liver or spleen. Sometimes there may be three or four zones of varying resonance at the base of the chest, the liver or splenic dullness being continued upwards to that over the collection of pus under the diaphragm. Just above this there may be a tympanitic note over a collection of gas above the pus, higher up a dull area indicating pleural effusion, and still higher the normal resonance of the lung. Although there may be no pulmonary signs at first, these develop later, due to the spread of congestion and inflammation to the pleura and lung. Sooner or later there may be pleurisy with a "rub," followed by effusion; there may be signs also of inflammation and perhaps some collapse at the base of the lung with rales and rhonchi, and particularly deficient entry of air and tubular breathing. Lower down, over a collection of gas below the diaphragm, there may be the coin sound or *bruit d'airain*. Leucocytosis is an important and almost constant sign. In late cases there may be bulging of the corresponding side of the chest, and later still oedema and even pointing of the abscess generally below the costal margin, either in front or behind.

DIAGNOSIS

The diagnosis of this condition is unfortunately difficult, and is too often seriously delayed. A good radiographic examination is invaluable; often there is shown a characteristic local elevation with fixation of the dome of the diaphragm. In some cases a collection of gas above the pus is also shown upon the screen. It must not be forgotten, however, that the retraction of a fibrosing lung may pull the diaphragm up so much and in such a way as closely to simulate the shadow of a subphrenic abscess. Similarly the stomach has been mistaken for a subphrenic abscess on the left side. In the hope of settling the diagnosis a large and long exploratory needle is generally relied upon, but unfortunately the needle often fails us, either getting blocked by thick lymph or missing the abscess. It failed in eleven out of eighteen cases so tried by Barnard. There is a far more reliable method of proving the presence or absence of a subdiaphragmatic abscess, and when in doubt in these grave cases, where a prompt decision is absolutely necessary to save life, this method should always be used. Under general or local anaesthesia an incision just large enough to admit the hand is made in the epigastrium, and the hand is passed in all directions above the liver. Within a few minutes the diagnosis is settled, and an abscess, either under the diaphragm or in the liver, is not only found but accurately located; it can then be safely and quickly drained below the pleural reflection and extraperitoneally, thus avoiding the grave risks of pneumothorax, empyema, and peritonitis.

Upon three occasions, after being asked to drain a subphrenic abscess, one of us used the epigastric incision, and proved that no abscess existed, although the radiograms had shown shadows which were thought to be typical. It is often almost impossible to distinguish empyema from a subdiaphragmatic abscess. In both, the cupola of the diaphragm is fixed, but in the former it is depressed, and in the latter elevated in a characteristic way, leaving the costophrenic angle transparent (Fig. 1).

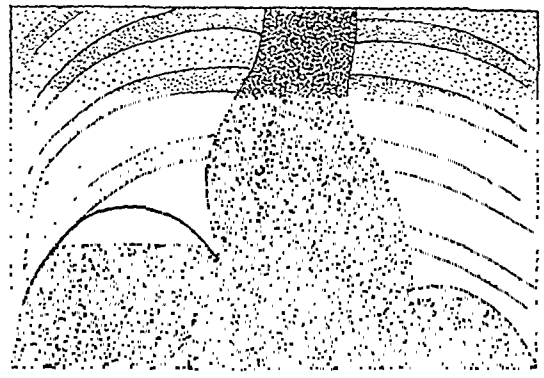

FIG. 1.—Diagram showing the radiographic appearances of a gas-containing subphrenic abscess on the right side. The right cupola of the diaphragm is pushed up and immobilized. The costophrenic and pericardiophrenic angles are not obliterated or opaque, as they would be if the pus had been above the diaphragm.

The exploring needle does not help in the distinction. Not uncommonly, empyema complicates a subphrenic abscess.

PROGNOSIS

In our experience, subphrenic abscess is much rarer than it used to be. Over a period of ten years since the war, the Guy's Hospital surgical reports record forty-nine cases, an average of under five cases a year. This is almost certainly due to earlier diagnosis and operation for perforated peptic ulcer and acute appendicitis, and to the better packing off of the subphrenic space and the avoidance of irrigation during these operations. The frequent adoption of the Fowler position has also helped.

TREATMENT

Without operation there is very little hope of recovery, although the abscess may drain imperfectly through the lung into one of the hollow abdominal organs or through the skin. The few patients who survive this tedious process are apt to become chronic invalids. The main ideal of successful operation is efficient drainage without risks either of pulmonary complications or of peritonitis. To attain this ideal every effort should be made to drain the abscess at its lower part, below the pleural reflection, and extraperitoneally.

The anterior abscesses, which are fortunately most common, often descend into the epigastrium or hypochondrium. They can be drained through an incision below the costal margin, but a counter-incision in the loin is sometimes also necessary. Posterior abscesses may be drained through the thorax, either by a subpleural or transpleural route. The cases cited below illustrate the frequency with which pulmonary complications follow the transpleural route, yet this still appears to be the common method of approach. It is interesting in this connexion to review Barnard's lines of treatment.

Barnard did not advocate early operation upon these abscesses, but preferred in most cases to delay intervention until the abscess had enlarged considerably and was well shut off. His reasons for doing so were that as the abscess enlarged the diaphragm was driven up, and the

lower part of the pleural cavity was obliterated or closed by adhesions. The abdominal viscera, on the other hand, were pushed down, so that when the transpleural operation was chosen the abscess could be opened through a lower spot in the thoracic wall. It is apparent from Barnard's case reports that the diagnosis of subphrenic abscess was not made until a late stage of the condition. He says that in fifty out of seventy-six consecutive cases an abdominal swelling was noticed as one of the signs of the abscess. Again, *x* rays demonstrated the abscess as a dark shadow in the only case in which they were used. Barnard preferred the posterior transpleural operation for large abscesses which had pushed the viscera down, but he was alive to the danger of producing pneumothorax and empyema by this route. He therefore took elaborate

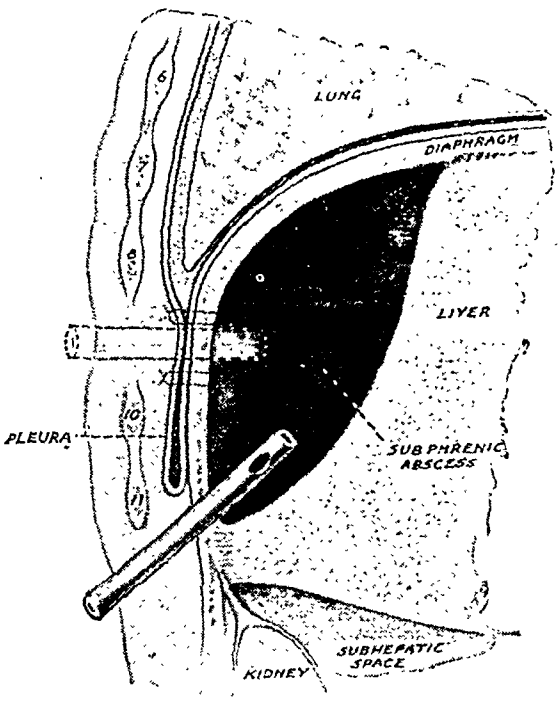

FIG. 2.—Subpleural and retroperitoneal drainage of a subphrenic abscess; a part of the twelfth rib has been removed, and the lower tube has been inserted through a horizontal incision in the diaphragm below the pleura. The upper shadowed tube passes through the pleura. This method is to be avoided, because pneumothorax and infection of the pleura may result even after all precautions have been taken to avoid them, and even when the pleura is adherent at the time of the operation.

precautions to prevent these complications. He got an assistant to push up the liver whilst he was incising the pleura. Then he sutured the pleura on the surface of the diaphragm to the parietal pleura, even although adhesions were present. Lastly, having incised the diaphragm, he sutured the latter to the intercostal muscles.

At the present time subphrenic abscesses are recognized at a comparatively early stage by improved methods of radiography, etc., and they call for treatment before the pleural cavity has become obliterated and the viscera pushed down to any great extent. It is particularly important to avoid the transpleural operation in these early cases, but even in late cases it is not so safe as the subpleural operation, pneumothorax with pleural infection having often followed, even when the lower part of the pleura has appeared to be safely obliterated either by nature or by art. Therefore the exploring needle should be inserted below the pleural reflection, which runs obliquely about an inch above the lower costal margin. The needle should be passed obliquely upwards and inwards. If pus be found the incision should follow the needle, the diaphragm being exposed and a transverse incision made through it below the pleura. Generally it is necessary to remove a portion of one or more ribs below the pleura in order to get adequate room (Fig. 2). Nather and Ochsner remove the whole of the last rib, but it is enough, and safer, to excise only the distal half, because the pleura often extends below the neck of the last rib, where it is liable to be wounded. The transverse incision through the diaphragm is made at the level of the first lumbar spine, and therefore nearly always well below the pleura. The peritoneum lining the diaphragm is carefully separated and pushed forward, and the closed points of long dressing forceps are passed just below and along the needle into the abscess. The forceps are opened gently to enlarge the opening, and a large rubber tube is inserted and stitched to the skin.

MORTALITY

Without operation the death rate of subphrenic abscess is over 85 per cent. With operation it used to be over 50 per cent.; in recent years, however, it has been reduced to about 25 per cent. Before long it should be further reduced by earlier diagnosis and better operations, especially with the avoidance, whenever possible, of pulmonary complications.

CASE I

R. B., aged 20, was admitted to Guy's Hospital on March 30th, 1930. On the 24th he had had pain in the region of the umbilicus, associated with nausea and vomiting; on the 25th the pain had travelled to the right iliac fossa and had got steadily worse; on the 30th the pain was excessive; the bowels had not opened for five days. On examination the abdomen was rigid all over, and particularly on the right side; there was no special tenderness in the right iliac fossa. Rectal examination showed tenderness in all directions. His temperature was 103° F., and pulse 120; the tongue was dry and brown. The abdomen was opened the same day through a lower right paramedian incision, and a gangrenous appendix was removed. The peritoneum was full of pus. The pelvis and the right iliac regions were drained through stab wounds. He did fairly well until April 12th, when his temperature rose to 102°. The right chest was rigid, and there was dullness over the lower part of it. On the 13th, the eighth space, on the right side beneath the axillary line, was aspirated and three-quarters of a pint of foul pus, containing *Bacillus coli* and streptococci, was removed. The following day another pint of similar pus was removed, and as there still appeared to be more, further operation was undertaken, a piece of the eighth rib removed, and a subphrenic abscess drained. The diaphragm was found to be firmly adherent to the parietal pleura. On April 19th he collapsed again, and was found to have a pneumothorax; air was sucking in and out with each breath, around the drainage. A larger drain was inserted and sealed to the thoracic wall with a rubber dam. Negative pressure was maintained by suction with Sprengel's pump, but he died the following day. At the subsequent examination the abscess cavity was found almost empty, and there was no empyema on either side.

CASE II

A man, aged 45, was admitted to Guy's Hospital on April 22nd, 1930, for a perforated duodenal ulcer with extravasation. The perforation was closed and the wound was drained, and everything went satisfactorily until about three weeks later, when the temperature went up and remained remittent, and about 101° F. in the evening. The man made no complaint of pain in his back, but there was dullness at the right base. The radiograms did not reveal any bulging up of the diaphragm, but only fixation of the right cupola. The leucocyte count was 20,000. A physician saw him and was a little uncertain as to the exact cause of the symptoms. A needle was inserted in the right pleura, without finding any pus; only a little clear fluid was withdrawn.

Under an anaesthetic on May 22nd, the patient lying on his left side, a large needle was passed obliquely upwards and forwards from behind and below the last rib. At the second

venture offensive brown pus was found. Then, through an oblique incision, the terminal half of the last rib was removed and the diaphragm cut horizontally; it was thickened and inflamed. Forceps were passed upwards and forwards along the needle into the abscess cavity, which was the size of an orange, and lying chiefly behind the right lobe of the liver. It was drained through a large tube, and the patient made a good and rapid recovery.

CASE III

T. B., a male aged 59, had had indigestion and attacks of vomiting for years. On November 1st, 1922, he was seized with sudden severe abdominal pain, accompanied by vomiting, and was admitted to Guy's Hospital on November 4th. The right upper quadrant of the abdomen was rigid, and there were signs of compression of the base of the right lung. The *x*-ray report stated: "Right diaphragm is greatly elevated and completely immobile. Left diaphragm moves well. Gas bubble above right lobe of liver." This abscess was explored transpleurally by resecting the tenth rib in the mid-axillary line, four and a half pints of fluid being removed. The patient died on December 11th, and at the post-mortem examination a large right empyema and collapsed lung were found. The subphrenic abscess was secondary to a perforated duodenal ulcer.

CASE IV

I. G., aged 33. A gastric ulcer was operated upon seven hours after perforation, suture of ulcer being done with suprapubic drainage. Eight days later pain was complained of below the left costal margin, and examination proved a "rub" at the left base. A straw-coloured fluid was aspirated. On the eleventh day a left subphrenic abscess was drained by incision below the last rib. On the fourteenth day there was rib resection for left-side empyema; the patient died on the twenty-eighth day.

CASE V

C. McC., aged 62 years, was admitted to Guy's Hospital on May 2nd, 1925, with a fifteen-hour history of acute pain in the upper abdomen. Laparotomy revealed a perforated duodenal ulcer. Suture with drainage of the peritoneum was performed. Three weeks later he had pyrexia with pain over the lower ribs on the right side. The white blood count was 20,000. *X*-ray report: "Right leaf of diaphragm is slightly elevated, movements greatly diminished. Slightly indefinite opacity at right base suggestive of pleural thickening, but no effusion seen. Left base and left diaphragm show no abnormality." Pus having been found by an exploring needle on June 11th a portion of the eleventh rib was resected on the right side; the lower margin of the pleura was found and sutured to the diaphragm. The diaphragm was then opened subpleurally and the abscess drained. He made a satisfactory recovery, and was discharged a fortnight later.

CASE VI

K. S., aged 38, was admitted to Guy's Hospital on September 12th, 1927, with fourteen days' history of pain in the left loin, with pyrexia. There was tenderness in the left loin and dullness at the left base of the lung, but *x* rays showed no abnormality. An exploring needle inserted through the tenth space located pus apparently below the diaphragm. A portion of the eleventh rib was resected and the pleural cavity opened; no pus was present. The pleura was closed and the diaphragm incised and a subdiaphragmatic abscess drained. One month later the pyrexia was still present, and pus was found by an exploring needle in the left pleural cavity; this was drained through the original wound. After a prolonged convalescence the patient left the hospital with a discharging sinus.

CONCLUSIONS

A review of the causes, symptoms, and diagnosis of the subphrenic abscess is given.

The treatment is discussed, and the posterior subpleural method of approach is advocated in order to avoid pulmonary complications.

Cases are cited illustrating the complications following the transpleural route. Cases II and V show the advantages of the subpleural route.

GENERAL OBSERVATIONS ON SEA-SICKNESS AND THE LABYRINTHINE THEORY*

BY

T. GWYNNE MAITLAND, M.A., B.Sc., M.D., D.PHIL.

MEDICAL SUPERINTENDENT, CUNARD COMPANY

The British nation, eminently seafaring, is conspicuous for its neglect of the study of sea-sickness. In consequence of this ignorance there is as much diversity of opinion about cause as there is about treatment. The very prevalent view that sea-sickness is a matter of mere nerves arises from the observations that vomiting sometimes occurs before the passenger has embarked, and also that sea-sickness is apparently so often controlled by suggestion. There are other views equally superficial which overlook the primary cause because of some casual feature which is unduly prominent. So it is with treatment. The layman, in the person of the old traveller or the bedroom steward, is always prepared with an "infallible remedy." Even the medical man, at sea as on shore, may have partial success with a favourite drug, and, turning a blind eye to failures, may become stereotyped in his advice. The underlying factors are altogether too inconstant for certitude. Personal adaptability, the subsidence of winds and waves—any one or all may make a remedy appear effective. Thus it is advisable that the would-be voyager, when urged to try so many "personally recommended cures," should bear in mind the poverty that lies in such wealth.

CONDITIONS AT SEA

It is exceptional to have seas continuing rough for a trip of six days. It is not uncommon to hear sailors speak of a wind as "blowing itself out"; rough days alternate with calm days; all the greater care is needed, therefore, in waxing enthusiastic over a specific remedy. The weather may have changed, the sea subsided, the first attack of vomiting have corrected the overtaxed digestion, or one's sea legs may have come to the rescue. For these reasons it is necessary to appraise all the accessory aids as nearly as possible in order to judge how far any particular remedy has contributed towards recovery. Care must also be exercised as to the denotation of sea-sickness in order to be quite sure that we are considering *sea-sickness* and not *sickness at sea*—cases of mere "nerves," those who are "sea-sick" when they step on the gangway or even (as in one case) when in sight of the sea, those who vomit merely in imitation or in consequence of the odour of vomiting, all in fact belonging to the readily suggestible, but who do not properly come within the scope of the inquiry.

THE SHIP'S MOVEMENT

Quite a large number of old travellers (ship captains among them) never acquire complete adaptability to ship movement. One ship surgeon of fourteen years' standing never put out to sea without, for the first two days, headache, mental confusion, and nausea, which went on to vomiting if the sea became rough. Long familiarity with one type of ship, in susceptible persons, may give undue confidence in their capacity as good sailors, only to have this rudely shattered as in the case of so many "old salts" when transferred during the war from big battleships and big liners to destroyers and trawlers. One may venture to say that with the exception of certain rare and mostly pathological cases, all normally constituted people are susceptible to some definite type of movement. Nevertheless sea-sickness has not the terrors for passengers it had in old times. Our parents may have been hardier, but the descriptions of crossings

* Read in the Section of Medicine at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

in the days of the sailing ships and early steamers make nauseating telling. The present-day liners, with their size, their exquisite balance, the diversion by exhaust of all unpleasant odours from engine and from galley, and the immense precautions with regard to cleanliness and comfort, make of the ordinary crossing a genuine rest and holiday. It is not possible for a ship to be so constructed as to keep an even keel at sea. A ship's stability, its reputation as a good sea boat, depends to a certain degree on its harmonic response to wind and wave. The tendency has lately leaned towards giant liners, as they are unaffected by the wave movement which smaller craft find definitely uncomfortable, although these big vessels, with a certain type of sea, may also roll and pitch to an unpleasant degree.

CAUSATION OF SEA-SICKNESS

An inquiry into the causes of sea-sickness was held with Group-Captain Martin Flack, Dr. J. R. Marrack, and Major Reid. The ship chosen has a splendid reputation as a sea boat, but fortunately for our investigations the outward journey was the roughest crossing experienced in it for over eight years. Major Reid was enabled, with a ship-movement indicator and his rate-of-turn gyro, to analyse into its components the movement of the ship in a head sea, twice registering a maximum pitch of 10 degrees; with a sea abeam, a maximum roll of 20 degrees was recorded. The yaw—a sort of "side-slip"—was also taken. In bad weather the rolling and yawing are interrelated. The observations not charted were the scend, or upward and total displacement of the ship, and the oscillation. Needless to say, the scending throughout the trip was always present, the others—pitch, roll, and yaw—varying in combination with it. The most unpleasant movement is what is called "corkscrew," when the seas are on the bow or quarter, a combination of roll and pitch on a basis of yaw and scend.

Major Reid's apparatus was able to register the time-frequency of the roll, pitch, and yaw, which will later be seen to have considerable significance when comparing ship movement with rotation experiments. Any statement of rolls exceeding 30 degrees should be received with caution. But even a big roll, if slow in development and change of direction, need not necessarily be unpleasant; the type that provokes sea-sickness is generally the suddenly unexpected arrest of movement and change of direction. Whatever the ship's movements may be, the passenger can only partially counteract it by bodily adjustment, since the movement takes place in so many planes. Lying "fore and aft" for roll or "athwart" for pitch is well advised, but no fixed position does more than give a relative measure of ease. Since the change of direction cannot be anticipated, the eye fails to pick up datum levels which will rectify the erratic information from the semicircular canals. In very rough weather, the ship's movement may not be provocative at all; the boat may not pitch, roll, or scend, for a wind of sufficient force may flatten out the waves. It is generally in the aftermath of the gale that the sea begins to rise.

The sea voyager, then, is submitted to movements from without which he bears ill, contending with others than those in the horizontal plane to which he is well accustomed in car and train. The experiences that have something in common with ship movement are those of a quick-moving lift, of the aeroplane in an air pocket, of the swings and mountain railways of the world's Coney Islands, and, perhaps most of all, of a camel, which rolls and pitches. All these have movements in other planes than the horizontal, but with a sensible duration in each; after a pause they abruptly pass to other planes. This is obviously entirely different from, say, the quick jerk up and down of the parade cavalry trot, which, although the abdomen is rudely shaken, has never been known to cause symptoms similar to sea-sickness. All movements such as these are altogether too short in duration to be provocative.

A number of subjects, eight in all, were examined for pulse rate, ocular imbalance, and blood pressure, before and after they were seated for fifteen minutes on the automatic trotting horse. They were all new to this experience, and were told not to rise to the movement, but relax in order to get the maximum of jolt from a rise and fall of the seat from 5 to 6 inches. In no case, although the abdomen was thus submitted to a fairly severe tax, was there change in any of the readings; the pulse rate was normal, and there were no symptoms of nausea, vertigo, or even headache.

The point to note with regard to the movements of the ship and of allied means of transport is that there is an appreciably long latent period before the development of symptoms. The threshold is lowered by a summation of stimuli, the symptoms even under bad conditions usually occurring after ten minutes, and often not before three or four hours have elapsed. This sharply distinguishes the genuine sea-sick type, whose distress is definitely due to the ship's movement, from those highly suggestible persons who retch the moment they set foot on the gangway, or are affected by the sound, the sight, or the odour of vomit.

SYMPTOMS

The symptoms differ very considerably from case to case. A list of these was drawn up and found to include for the most part blurred vision, a feeling of visual uncertainty, giddiness, coldness of the extremities, headache (variable in position), cold sweats, hot sweats, mental confusion, lethargy to any effort, mental or bodily, salivation, nausea and vomiting, occurring in any order within certain limits. The cases were roughly classified as severe, moderate, and slight; because vomiting is regarded as a classic symptom of sea-sickness it was made the standard for severe cases; those cases with one or two not very distressing symptoms, such as vertigo, lassitude, etc., were put down as slight; headache, nausea, and any other symptoms which were definitely uncomfortable were placed in the moderate group. The examinations were made in conjunction with Dr. Martin Flack, the result being: severe 86, moderate 11, slight 27.

Symptoms with their Frequencies
March, 1930

Vomiting	86	Hot and cold sweats in turn	5
Vomiting without nausea	34	"Feeling of heat"	1
Vomiting with nausea	52	"Feeling of cold"	1
Nausea	74	"Sinking feeling"	2
Nausea without vomiting	22	Lassitude	6
Headache	63	Light-headed	3
Vertigo	47	Constipation	2
Mental confusion	32	"Acid stomach"	1
Pallor	40	Thirsty	1
Blurred vision	17	Pain in back	1
"Hot sweats"	25	Diplopia	1
"Cold sweats"	5	Asthma	1

A Compilation made by One Surgeon over the Period 1924-26

Vomiting	320	Vomiting without nausea	60
Nausea alone	240	Lassitude	44
Headache	165	Blurred vision	40
Vertigo	122		
Abdomen discomfort	97		

PHYSIOLOGICAL TESTS

With regard to the simple physiological tests that were practicable, three symptoms were appropriate. The first was blurred and confused vision. Dr. Flack deals with this aspect, examining the claim that ocular disturbance is a primary factor in sea-sickness. It is well known that certain patients (keeping the eyes on a datum level, such as the horizon) derive considerable benefit by closure of the eyes, by bandaging one eye, by wearing coloured glasses, or even by paralysing accommodation with a local application of atropine. That these remedies fail in the great majority of cases is now admitted, but that the eye may be a contributory factor

is not to be denied; the question, however, is to what extent. The Bishop Harman apparatus was therefore used to test imbalance before and after sea-sickness, and before and after experiments in rotation with the Bárány chair. There was little doubt that a large majority of early cases were associated with an initial heterophoria, and that this definitely increased with the development of sea-sickness. Nevertheless, the monoculars did not escape sea-sickness, neither did the zero Bishop Harman cases, so that perfect eye balance is not necessarily a protection, nor is single vision.

44 sea-sick cases showed B. H. readings above 3.
66 sea-sick cases showed B. H. readings below 2.
4 non-sea-sick cases showed B. H. readings above 3.
24 non-sea-sick cases showed B. H. readings below 2.

That the eye can be involved without the cerebral effort of visual attention is demonstrated by rotating the subject in the Bárány chair with closed eyes. Nystagmus is very apparent under the closed lids, but the confusion and vertigo are considerably increased when the eyes are opened, owing to the visual information still further conflicting with the other proprioceptors and extroceptors. In sea-sickness the closed eyes undergo a constant and compensatory adjustment of equilibration, despite the absence of any object in the visual field. This adjustment acts, not only in correspondence with the waves of pressure in the endolymph of the labyrinth, but to a lesser degree with the tonic neck reflexes and the tactual sensations from the parts involved in posture. Such bodily adjustments of eye and musculature have all been described by Magnus,[1] under the headings of "tonic neck reflexes," "tonic labyrinthine reflexes," and "optical righting reflexes."

The next investigation was that of the pulse rate and blood pressure. The signs and symptoms themselves indicated the need of such observations. Some subjects showed extreme pallor and slight collapse, others a heightened colour, sweating, and a dilated pupil, suggesting either a parasympathetic or a sympathetic disturbance. Sometimes these alternated, parasympathetic symptom following sympathetic. In others it would seem as though the cases displayed certain features of each. It was often difficult to decide on the type of disturbance. In the better-defined cases the pulse rate showed either a bradycardia, with a drop in rate when the subject stood up, or a tachycardia still further increased on standing. The blood pressure showed a corresponding coincidental change, some cases demonstrating a blood pressure with a systolic reading below 100, and others with a systolic pressure above 140 when the normal was 120 or thereabouts, all being young and healthy people. These are shown in the following tables.

Alteration of Blood Pressure after Certain Prominent Symptoms

Symptoms	Blood Pressure		No Change
	Fall	Rise	
Severe	20	16	8
Moderate	6	—	—
Slight	2	3	3
Alteration of Blood Pressure, with Severity of Symptoms			
Vomiting (severe)	21	14	9
Nausea	17	11	24
Headache	20	12	7
Giddiness	10	9	6
Confusion	10	4	4
Cold extremities	—	—	—
Hot sweats	9	8	3
Other symptoms	16	16	14

Last of the observations were the biochemical tests. Three years ago, after some interesting statements on sea-sickness by Dr. Oriel in the *Lancet*, there followed in the *British Medical Journal* an extraordinary number of conflicting opinions. Dr. Oriel's results seemed in sharp conflict with expert opinion. They were interesting and unorthodox, but perplexing in that a biochemical irritant, a condition of ketosis, was suggested as the possible cause of sea-sickness. The question to investigate, then, was whether ketosis was invariably present as a cause of the symptom of sea-sickness, or whether it was an effect of the vomiting or of starvation. Dr. Marrack, on two separate Atlantic trips, undertook to make some examinations on cases of sea-sickness prior to vomiting, after vomiting, and also on some non-sea-sick controls. The report of this investigation is made the subject of a separate paper by Dr. Marrack (p. 178).

Other Explanations of Cause

Many views of the cause of sea-sickness, though aired in the medical press, hardly deserve consideration, since they are conjectures only, and are supported by neither clinical observation nor experimental evidence. Such are the views of the primary importance of cerebro-spinal ebb and flow, cerebral congestion and anaemia, the varying pressure changes in hepatic circulation, the long omentum; these possess only a speculative interest. Then there is the opinion that is based on the success of treatment. Respiratory drill is the result of the view that the causal agency in sea-sickness is respiratory arrhythmia. In the first place this arrhythmia is not very marked except in highly agitated individuals, and is at variance with the fact that on shore, except in very abnormal subjects, no amount of distress, terror, or any emotion, brings about symptoms such as vertigo, nausea, or vomiting. In the second place, directing attention away from the dreaded object to some task or effort requiring attention occasionally succeeds. In the third place, even making every concession, the drill is of service to the very few, usually only those of apprehensive type; for that reason it has fallen into disrepute. Lastly, like so many remedies, it depends too largely on personal suggestibility to be generally valuable.

Dr. Poulton, in his interesting observations on the causes of nausea, in the Oliver-Sharpey Lectures for 1925, on certain visceral sensations, considers the locality of nausea to be in the back and lower part of the throat, and that it is due to a condition of tension. He describes the sensation as one of sinking in the throat, and views the condition as caused by a tug or distortive action of the oesophagus on its fixed portion at the rigid framework, the skull and vertebral column. The sensation of sinking he ascribes to a rise of tonus of the stomach wall. He produces experimental evidence to show that the stomach may actually fall, coincident with the sensation, and that bracing up the abdomen may wholly check it. Dr. Poulton considers that the nausea of sea-sickness is attributable to the movement of the ship, particularly by its retardation during the latter part of the descent. He is not prepared to say how far the acceleration at the beginning of the ascent may also account for it. This is a very reasonable presentation of the possibility of a peripheral factor in the production of nausea. That it may be a contributory element one is prepared to admit, but the hypothesis does not explain why nausea may be extreme in the very sea-sick patients who keep to their bunks or who wear a tight belt. With regard to the locality of nausea it is, as Dr. Poulton states, most difficult to get definiteness of opinion. Many describe it as vaguely extending over the upper part of the chest and throat; that the pharynx is here involved is probably due to its extroverted association with the pharyngeal reflex of vomiting.

THE LABYRINTHINE THEORY

The normal reactions of the vestibule are responsible for righting reflexes which compensate active displacements of the body. They are excited not so much by abnormal postures of the body as by movement, its initiation, its cessation, its acceleration, and its retardation. The loss of the associated reaction (the righting reflex) in the airman when flying, all unawares, upside down in a cloud, is evidence that the saccule and utricle of the labyrinth have lost their one-time delicate appreciation of static relations, so that the function of the labyrinth in man is now almost entirely confined to the semicircular canals.[2] The righting reflexes evoked by vestibular excitation are the same as those involved in the general static reactions; they are the extraocular compensatory adjustments, and the statokinetic reflexes from the neck and body as a whole. The musculokinetic system differs from the labyrinth in that it is aesthetic, and subject to inhibition, whereas the labyrinth has no associated labyrinthine sensation, and is entirely outside voluntary control. The musculokinetic reflexes therefore resemble a great many other reflexes, such as the conjunctival and the pharyngeal, which can be inhibited. The rider, when thrown from his horse, must inhibit these reflexes, which may destroy him, and the diver must deliberately counteract these influences the moment he takes off for a head dive. The statokinetic reflexes indirectly excited by the vestibule are then subject to voluntary control, which may explain certain facts in connexion with immunity from the after-effects of excessive and repeated stimulation.

It does not seem to be clearly understood how limited is the range of effective vestibular response. A long ancestry of adaptation to a stable environment has not fitted the vestibule with a defensive mechanism against some types of excitation which cause complete disorientation. From the very nature of lymphokinesis it will be realized why continuous rotation may fail to register, or at the cessation of rotation why movement of the endolymph, still continuing, may transmit information which is in conflict with that of the other exteroceptors and proprioceptors. When the labyrinth is destroyed, as it is in some deaf mutes, there is no longer a vestibular impulse, and in consequence neither conflict nor disorientation. The inherent failure of the labyrinth to register certain kinds of excitation bears witness to the body's limited ancestral experience of movements other than those self-initiated. Waltzing is no exception to this, inasmuch as, though at first self-initiated, it afterwards depends on the momentum which ensues, and which thus places it in the type of movement imposed from without.

There is considerable confusion, then, as to the proper function of the labyrinth. Nystagmus and postural and kinetic deviation are frequently regarded as if they were normal responses, whereas they are an expression of dysfunction and complete disorientation. It is nevertheless true that these, and not the normal responses, are material for the clinician, for paradoxically it is only by the abnormal response that the normality of the vestibule can be determined.

The tests employed to determine the integrity of the vestibule are those of caloric douching, of galvanic stimulation of the ear, and of body (= head), rotation; they are all abnormal or unusual excitations, and in the normal labyrinth bring about disorientation. The vestibule alone of all the organs engaged in the function of equilibration is abnormally susceptible to this kind of excitation, and the above reactions follow immediately on cessation in the case of rotation, and in a few seconds after the initiation of caloric douching and galvanic stimulation; they are called the primary reactions, and in the case of rotation usually disappear in less than thirty seconds. Apart from these primary and abnormal reactions there are secondary signs and symptoms depending upon the severity of the experiment and the susceptibility of the subject, and they continue after the primary reactions have passed away, the symptoms sometimes lasting for twenty-four hours. The secondary signs are a rise or fall of blood pressure and of pulse rate, and heterophoria; these signs rarely persist for more than thirty minutes. The secondary symptoms are variable, but vertigo, nausea, and headache are common. These secondary signs and symptoms are unquestionably evidence of irradiation, which is due either indirectly to the immediate results of excessive stimulation from the conflict brought about by nystagmus, postural and kinetic deviation with other exteroceptor and proprioceptor impulses, or directly to the excessive vestibular impulses in and by themselves. They are in no sense true reflexes, despite the ability in animal experiments to obtain invariably such vasomotor, cardiac, and respiratory effects, along with intestinal peristalsis, nausea, and vomiting.[3] They are no more specific than are other very frequent examples of irradiation.

THE SEMICIRCULAR CANALS AND RELATIVE SUSCEPTIBILITY

Both experience and experiment indicate the remarkable difference in the secondary effects after stimulation of the vertical, as compared with the horizontal, canals. To adequate and normal stimulation the verticals respond as effectively as do the horizontals, but for excessive stimulation there is a noticeable difference. It is unusual for waltzing, merry-go-round movement, and all such horizontal rotation to cause these secondary signs and symptoms, except in very rare cases, whereas scenic railways, swings, lifts, a rough sea, affect unpleasantly a large number of people. In experiments with the Bárány chair, in which the subject is seated with the head in different planes, according to the canals chosen for excitation, it is found that the abnormal excitation of twelve rotations in the horizontal for most people causes little discomfort, though the primary responses are more pronounced than when the vertical canals are tested. Twelve rotations, however, of the latter cause intense discomfort, the sense of disorder is overwhelming, and nausea and vomiting are quite common.

In attempting roughly to group subjects according to their susceptibility to abnormal excitation, it is remarkable how few display secondary effects from horizontal rotation. Only two of the many subjects showed a response; one vomited, and the other (the ship surgeon previously mentioned) felt malaise for twenty-four hours afterwards. Such persons so affected are usually subject to train- and car-sickness, and dislike waltzing. Then there is a large number who even enjoy these movements, but are upset by the swings, scenic railways, fast-moving lifts, and passenger ships in a moderately rough sea. The next group are not upset by the foregoing, but succumb to a torpedo-boat destroyer or a trawler in a gale, and to excessive vertical canal stimulation by rotation or caloric douching. Lastly, there are the pathological cases, the deaf mutes with functionless labyrinths, who show neither primary nor secondary effects in response to any kind of excitation.

NYSTAGMUS AND VERTIGO

The only normal and functionally useful reflex between the vestibule and the eye through the medium of the nuclei of the third, fourth, and sixth nerves is the eye-righting reflex. Owing, however, to the objective evidence of nystagmus arising from abnormal excitation of the vestibule, this connexion between the eye and the vestibule has been called the nystagmic circuit. The disorientation

associated with this abnormal excitation has been considered to be due either to a conflict from the disorderly exteroceptor, the visual impulses, or to the disorderly proprioceptors—the extraocular impulses—rather than to the disorderly vestibular impulses, in and through themselves. That it is not entirely dependent upon the former or visual impulses is clear from the fact that vertigo may still occur on shutting out the visual field by closure of the eyes; that it is not entirely dependent on the extraocular impulses is evident from two observations, the first being that after the disappearance of the primary reactions—that is, nystagmus, postural and kinetic deviation—vertigo may still persist; the second being that vertigo may follow abnormal excitation of the vestibule in the absence altogether of the primary reactions. Malan[4] of the Italian Air Force has observed that nystagmus and the primary reactions after abnormal excitation of the vestibule by rotation may, after a time, fail to appear on frequent repetition of the rotation experiment. This observation is in accord with my own experience, but, unlike Malan, I do not consider this is due to fatigue, but believe that it depends on cerebral control, an increasing ability to inhibit the effects of the abnormal excitation of the vestibule.

It is in most cases easy to curtail the time limit of nystagmus by asking the subject of the experiment to focus his vision persistently on some near object, and the same result observed by Malan in his subjects will, in due course, occur by a deliberate act of concentration rather than by an effort of self-preservation and eye fixation acquired, little by little, to eliminate the unpleasant effects of nystagmus. This same feature is associated with nearly all superficial and some organic reflexes, which, as stated previously, may come under cerebral control. The opinion has been advanced that the vestibule can have no relation to sea-sickness because nystagmus has not been observed in sea-sickness, while it is inevitable in chair rotation. This is erroneous, and is an entirely inadequate statement, and the basis on which the comparison is made has no norma. Rotation, when conducted so as to simulate ship movement, can produce the syndrome of sea-sickness without any of the primary reactions. Two errors in the argument depend on failure to collect evidence as to the time periods of the various ship movements, such as the pitch or the roll, and on ignorance of the importance of choosing for abnormal excitation the same canals that ship movement excites—that is, the vertical canals. With regard to the time element, this can be approached from the point of view of the time of ship movement, as compared with the time taken for the usual experiment with horizontal rotation. The most vertiginous of simple ship movements is the pitch, which in one phase rarely exceeds five seconds, only a third of the time taken by eight continuous horizontal rotations, which occupy sixteen seconds. To simulate the pitch, three rotations only should have been made, but then nystagmus would not have appeared in most subjects. In the next place, the pitch throws excitation on the vertical canals so that the comparison should have been instituted between ship movement and excitation of the vertical canals rather than with the horizontal. Had this been done another remarkable fact would have been forthcoming, and that is that eight rotations in the verticals produce a period of rotatory nystagmus of six seconds, or vertical nystagmus of eight seconds, according to the position of the head, against fifteen seconds of horizontal nystagmus. It can now be understood why three continuous rotations only of the verticals are unlikely to elicit the primary reactions such as nystagmus. Neither the individual phases of a pitch or roll on the one hand, nor a corresponding period of vertical canal rotation on the other, will therefore cause primary reactions, but it is true of all these excitations that if they are repeated again and again the secondary reactions will almost unfailingly occur. Thus it is that the experiment of rotation with the head 120 degrees forward or 60 degrees backward for three continuous revolutions, including a pause of two seconds with the head brought to the erect in the interval, continued for two to four minutes, will cause these secondary reactions without the primary ones.

Of the eight out of the fifty-two subjects who consented to this variant to the usual experiment of the eight continuous rotations, all but two were nauseated, with mental confusion and headache, and they showed the physiological reactions in blood pressure and pulse rate changes, together with imbalance. There is therefore the closest resemblance between ship movement and rotation experiments when done in this way. In both there is a latent period, and both depend upon a summation of stimuli causing the secondary reactions—the syndrome, in fact, of sea-sickness.

The results of caloric douching dispose of the possibility of any visceral or somatic origin of sea-sickness. The same train of symptoms occurs as after rotation, but with caloric douching the head and body remain fixed throughout the experiment. That does not preclude the possibility of the visceral element, as in ships or lifts, acting as an accessory factor and aggravating a disorder already in being from bulbar irradiation. There are, in fact, no exteroceptor or proprioceptor impulses which may not directly or indirectly assist in the development of secondary signs and symptoms, but there are few cases, and exceptional ones, where such impulses act in and through themselves; for the most part, they play the part of signalizers. It is for the above reasons that overemphasis of the causality of the nervous and apprehensive factors of auto-intoxication by dyspepsia and constipation appears disingenuous. These, with ocular susceptibility, the toxaemia of tobacco, alcohol, and of the menopause, derangement of the cerebral circulation by mitral disease, and very many other conditions, may render the subject abnormally susceptible to this type of movement, or may aggravate the disorder once set up.

TREATMENT OF SEA-SICKNESS

For the therapy of sea-sickness it is therefore obvious, as with every other type of dysfunction, that not one of these factors can be omitted from consideration. From this it must appear superfluous to state that suitable measures against these may, and often do, avert an attack. But the matter does not rest always thus simply. In the failure so to avert sea-sickness, having taken all reasonable anticipatory measures, we have still the problem of its treatment when established. There is, of course, the treatment by direct and indirect methods of suggestion, with a certain amount of success to its credit, but with failure also, as is self-proclaimed in the ever-increasing number of advertised remedies. That these latter meet with both success and failure is due to a lack of discrimination, and it is imperative that a surgeon should not label his case "sea-sickness" and proceed to prescribe the last and most fashionable remedy. If he does so he will meet with some success, but also with inevitable disappointment, which will display his ignorance of the varying and conflicting manifestations of the disorder.

An examination of the secondary reactions is therefore obligatory, but it requires effort and a study of the case. That these reactions present anomalies has already been apparent in the analysis of sea sick cases, but is still more obvious in that of rotation cases. The statement for specific therapy will not be complete without a brief summary of these experiments.

ANALYSIS OF SECONDARY REACTIONS

In order to analyse the secondary reactions it was decided to record the results from eight continuous rotations on fifty-two volunteers, as offering a wider field for research, only eight having consented to the variant of two-minute interrupted rotations. The subjects were all healthy. All but twelve were between the ages of 17 and 30. Of the twelve, the ages ranged between 40 and 52, ten of these with a long sea service, and two with air service. The primary reactions, being irrelevant, were not recorded.

The results were those usually found in sea-sickness, the blood pressure taken for convenience as the chief vasomotor reaction, and the symptoms and signs were tabulated alongside as follows:

Systolic Blood Pressure	Symptoms and Signs	Nil
Rise	... 13	13
Fall	... 8	12
Unchanged	... 2	6

It will be observed that just half of the subjects showed a rise, indicating that the experiment was not too severe. Twenty showed a fall, and eight remained unchanged. Some of the twenty-six subjects were possibly apprehensive, and thirteen of these showed symptoms. Another curious feature is that while twenty showed a drop in blood pressure, twelve of these apparently showed no signs or symptoms. Of those whose blood pressure remained unchanged, eight in number, six were long-service Navy men who remembered being sick only as young lads. One of the eight was an airman who, for later and more drastic experiments, remained abnormally insensitive, though he showed the usual primary vestibular reactions. Three long-service Navy men showed a fall in blood pressure, without symptoms, so they said; these admitted susceptibility in heavy weather.

An examination of the sea-sick cases reveals the fact that the number of cases with a fall in blood pressure exceed those with a rise—twenty-eight with a fall, and nineteen with a rise. In the rotation experiments, on the other hand, there were thirteen with a rise and eight with a fall. There is a column headed Nil (no symptoms) showing that rotation influenced blood pressure without causing symptoms in twenty-five cases. The analysis of sea-sick cases shows no parallel column, but it is reasonable to assume that a great many voyagers might exhibit the same blood vascular reaction without necessarily exhibiting symptoms, and would therefore not come under notice in the ordinary way. It should also be noted that in eleven out of the fifty-eight sea-sick cases no change of blood pressure was exhibited.

CONCLUSION

This presentation of the subject of sea-sickness is not intended to be destructive of all existing remedies. It is rather directed against the assumption that any drug or method of treatment is infallible, and is incidentally intended to impress on the ship surgeon the need for careful appraisement of type, and, when prophylaxis fails, analysis and evaluation of signs and symptoms. Only after this can he avoid drugs and methods which are definitely contraindicated. Intervention is sometimes unwise, and sea-sickness may occasionally be a blessing; on the other hand, relief can be confidently offered to urgent cases from among the many valuable remedies which may be clearly indicated.

NOTE ON SEA-SICKNESS*

BY

GROUP CAPTAIN MARTIN FLACK, C.B.E., M.A., M.B.

DIRECTOR OF MEDICAL RESEARCH, ROYAL AIR FORCE

Experience has shown that there is little connexion between a history of sea-sickness and the possibility of being air-sick, except in persons who are invariably severely sea-sick. Candidates for aviation, therefore, are not asked whether they are subject to sea-sickness, but whether they are subject to severe sea-sickness, as well as unduly sensitive to rotary or uneven movement, such as those on roundabouts, switchbacks, or scenic railways, etc. They are also questioned as to train-sickness and tram-sickness.

To determine suitability for aerobatics, the following test has been devised. The subject is seated in a rotating chair, and, while sitting as in an aeroplane, with eyes open and head in the best possible position—that is, looking inside the knee further from the direction of spin—is subjected to a relatively fast spin, ten times in twenty seconds. The pulse rate and arterial pressures are taken just before the spin, and immediately afterwards. In special cases, the effect upon the ocular muscle balance is also investigated. The main results of the test, which was worked out in the Royal Air Force Medical Research Laboratory in 1922–24, may be summarized as follows:

1. In fit pilots, particularly those accomplished in aerobatics, rotation produces but little effect upon the pulse rate or arterial pressures, and does not disturb the eye muscle balance.

2. In cases subject to vertigo, nausea, or vomiting, rotation produces a marked rise in pulse rate and systolic and diastolic pressures; the eye muscle balance is also greatly disturbed in such cases.

3. In subjects liable to fainting, rotation produces marked pallor, and a characteristic fall in the diastolic pressure.

4. In highly strung subjects, liable to develop an anxiety neurosis, there is a marked anticipatory rise of pulse rate and systolic blood pressure prior to rotation, which may or may not be further affected by rotation.

5. In practice, it is found that subjects may tend to exhibit a combination of abnormal responses, but the main criterion is the fact that the satisfactory pilot is relatively stable in all his responses.

A relevant case as regards sea-sickness is given here. The subject was a naval officer who had suffered from sea-sickness in submarines and torpedo-boat destroyers.

Case showing Liability to Vertigo, etc.

The subject was 24 years old, and the official report stated: "On each occasion that I have taken this officer in the air for the purpose of dual instruction, after fifteen minutes he has collapsed through sickness." In an examination on June 20th, 1923, before being placed on the rotating chair his pulse varied from 6–8 in five-second periods, his systolic blood pressure being 128 mm. Hg and his diastolic 82 mm. Hg. After rotation, his pulse, in five-second periods, was 11, 12, 11, 12, 11, 12, and did not fall back below 10 in one minute; the systolic blood pressure was 172 mm. Hg, and the diastolic 98 mm. Hg. The nystagmus time was normal, and the ocular muscle balance was greatly disturbed.

* Read in the Section of Medicine at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

It will be noted in this case that although the nystagmus time was normal, the ocular muscle balance was greatly disturbed, as well as the pulse rate and blood pressures.

The above results on experimental nausea and vertigo have since been confirmed, as regards disturbance of pulse rate and blood pressures, by M. H. Fischer, whose results are quoted in his article on sea-sickness in the *Handbuch der Normalen und Pathologischen Physiologie*, 1930 (p. 495), where a relatively full bibliography is also given.

In the opportunity recently afforded by the Cunard Company to investigate certain aspects of sea-sickness, it was felt that it would be of interest to see how subjects exposed to the prolonged uneven movements of the sea in rough weather reacted as regards maintenance of ocular poise, pulse, and blood pressure. In all 162 cases were examined. Members of the crew who had not been sea-sick for many years were used as controls. Ability to maintain ocular poise was tested by means of the Bishop Harman diaphragm, working, for the sake of convenience, with a fixed pupil distance of 65 mm. Under these conditions, work in connexion with visual judgement in pilots has shown that a reading of 3 or under may be termed good, of 3 to 4, average, above 4, poor.

Unfortunately, one voyage was relatively smooth, and of short duration, while on the other voyage the rough weather started before a sufficient number of observations could be made on subjects prior to the occurrence of symptoms. It was not possible to make more than a few experiments with the rotating chair, as in candidates for aviation. It was found, however, in the few cases examined that good sailors were not greatly disturbed by the chair test, while in one passenger who was feeling "squeamish" it induced vomiting.

The results obtained may be briefly summarized as follows:

1. There was no marked deviation from the normal of the pulse rate or blood pressure in forty-two members of the crew who had never been sea-sick, or had not been sea-sick for over ten years. As regards ocular poise, five were monocular. The others all showed exceptionally good eye muscle co-ordination, giving a Bishop Harman reading of 3 or under, with the exception of one man who had previous damage to the eyeball not affecting the vision (reading 4½). This confirms the results as regards air-sickness in over one hundred pilots (controls) who had had great experience in aerobatics.

2. In many of the passengers and crew who were sea-sick there were definite signs of ocular muscle imbalance with the onset of the first symptoms of sea-sickness. Readings of 4 to 8 were frequently obtained. This lack of power of co-ordination of the eye muscles was found to have developed in several who had been examined prior to the onset of symptoms, and during sea-sickness, and to have passed away in others who were examined while sick and after the symptoms had passed off. Normally, sensations from the labyrinths and kinaesthetic sensations from the neck muscles produce deviations of the eyes of a compensatory nature, which tend always to preserve the same visual field as would pertain if the head and neck were in their normal positions. Therefore it would appear probable that the induced eye muscle imbalance represents in these cases a defective compensatory poise of the eyes produced reflexly by stimulation of the labyrinths, and that its production in eyes previously well balanced, or the aggravation of imbalance in eyes previously suffering from a certain degree of this defect, is one of the predisposing causes in the early onset of symptoms.

3. Concomitantly with, or, more generally, following, the onset of eye muscle inco-ordination, there is a marked vagal effect causing slowing of the pulse and a fall of blood pressures, both systolic and diastolic. The immediate effect on the pulse and blood pressure would appear to vary as to whether the individual is primarily sympathicotonic or vagotonic; in some cases an increase in pulse rate and blood pressure is found with the onset of symptoms; in others the fall in pulse rate and blood pressure seems to occur almost at once. The vagal effect upon the pulse and blood pressure tends to last longer than the effect upon the eye muscles. Below are given particulars of a number of illustrative cases which were examined on two or more occasions, the cases of J. M. and A. M. being also quoted in detail by Dr. Marrack in his paper.

Further experiments are required to confirm the results tentatively set forth in this preliminary communication.

Case	Bishop Harman Reading	Pulse Sitting	Blood Pressure		Date	Remarks
			Systolic	Diastolic		
J.M.	1	66	126	78	30/3/30	Feeling fit. No acetone.
,,	3	56	108	64	31/3/30	Marked acetone. Been sick.
,,	1	66	120	70	5/4/30	Feeling recovered.
A.M.	½	84	132	74	30/3/30	Feeling all right.
,,	4	72	132	74	31/3/30	After being sick.
,,	3½	80	104	64	1/4/30	After being sick.
,,	2	72	122	78	5/4/30	Feeling better.
H.M.	4	78	122	72	1/4/30	Following vomiting.
,,	1½	78	120	80	9/4/30	Recovered.
R.McC.	4	67	102	60	30/3/30	Squeamish. Acetonuria few hours later.
,,	1	84	108	76	8/4/30	Feeling recovered.
J.A.T.	4	80	132	74	30/3/30	Feeling queer Acetone present, sea sick.
,,	5½	84	116	66	31/3/30	Sent hospital. Acetonuria marked.
,,	3½	66	144	96	6/4/30	Feeling better. No acetonuria.
W.S.	Over 10	80	128	68	30/3/30	While sea-sick. No acetonuria.
,,	10	72	128	72	8/4/30	Feeling "fine."
M.F.	2	86	120	80	30/3/30	Feeling squeamish.
,,	3	82	106	62	31/3/30	Following sickness.
,,	1	66	120	80	8/4/30	Recovered.
O.A.	3½	84	154	84	1/4/30	Following sickness.
,,	1	78	128	60	8/4 30	Recovered. Seven days later.
J.A.G.	3½	78	118	66	16/4/30	All right.
,,	8	72	136	70	20/4/30	Beginning to feel queer
E.B.	1½	78	110	70	16/4/30	All right.
,,	4	90	103	64	20/4/30	Thick in head No vomiting.
G.B.	3	72	110	76	16/4/30	All right.
,,	6	78	112	70	20/4/30	Sea rougher. Not so good.
V.H.	2½	78	114	78	16/4/30	All right.
,,	6	90	98	58	20/4/30	Sea rougher. Headache developing.

Conclusions

Provisionally it may be concluded that:

1. Sea-sickness is predominantly of vestibular origin due to uneven movement.

2. In certain cases where the labyrinths are unduly sensitive vomiting may occur early, due to reflex stimulation of the vagus motor fibres to the stomach. Such cases are of the type which are also liable to air-sickness.

3. In cases of sea-sickness where the labyrinth cannot be deemed unduly sensitive, its stimulation early induces or aggravates a degree of ocular muscle imbalance, which, combined with the continued stimulation of the vestibular apparatus, serves to provoke further symptoms.

4. Generally speaking, subjects in whom eye muscle imbalance is not induced or aggravated do not suffer from sea-sickness, although a slow pulse and a lowered blood pressure may cause a feeling of "limpness."

KETOSIS IN SEA-SICKNESS*

BY

J. R. MARRACK, D.S.O., *M.C.*, M.A., M.D.

CHEMICAL PATHOLOGIST, LONDON HOSPITAL

The theory of the presence of a metabolic disturbance in sea-sickness is mainly based on the work of Oriel (1927); his observation that ketosis may occur before the onset of vomiting suggests the possibility that this ketosis may either itself be the cause of the sickness or evidence of a metabolic disorder which is the actual cause. It is therefore of interest to find how frequently ketosis appears before vomiting begins, and to measure the degree of ketosis when it does occur, in order to decide whether it is sufficiently severe to account for symptoms.

The subjects of this investigation were mainly passengers and crew on two Cunard liners during two rough passages from Liverpool to New York; a few observations were also made on two calm passages from New York to Southampton.

Incidence

With one exception, ketosis occurred in all subjects within twenty-four hours after actual vomiting began. This one exception was a woman, aged 54, who stated that she suffered from "stomach trouble," associated with vomiting at other times; it is possible that her sickness was not "sea-sickness."

On the other hand, considerable disturbance apart from actual vomiting may occur without ketosis; one subject, J. M., had continuous nausea for two days on one voyage without ketosis, although on a later voyage, when actual vomiting occurred, ketosis appeared after twelve hours. Another subject, A. M., had ketosis immediately after vomiting on one voyage, but on a subsequent one ketosis was never detected, although she felt unwell throughout the voyage and her blood pressure was low.

Relation of Ketosis to Time of Vomiting

Figure 1 shows the relation between the intensity of the nitroprusside reaction and the time before or after vomiting at which the observation was made in a series of cases. A pink colour developing in about ten minutes

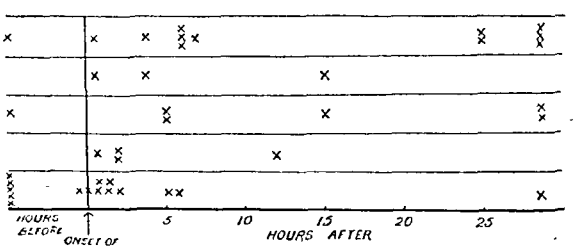

FIG. 1.—Relation between the intensity of the nitroprusside reaction and the time at which the observation was made before or after vomiting.

was classed as (1), and an almost black colour as (4); (2) and (3) were intermediate degrees. As Oriel found, ketosis may appear before the onset of vomiting. The subject with a (4) reaction before vomiting appeared quite well at the time. Otherwise the cases with early ketosis did not appear different in any way from other cases. However, the figure shows that as a general rule ketosis developed *after* vomiting had started, and might still be moderate after twenty-four hours' vomiting.

* Read in the Section of Medicine at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

Amount of Acetone Bodies Excreted and Relation to Carbohydrate Metabolism

Figure 2 shows the ammonia excretion of two sea-sick subjects; A. M. took a small amount of carbohydrate food, A. S. was starved. The ammonia affords a fair measure of the ketone bodies in the urine, as is shown by the estimates of ketone bodies and organic acids made on some of the urines. Although the ketosis in the first case was slight it is difficult to regard it as due to carbohydrate starvation, as it was detectable at the

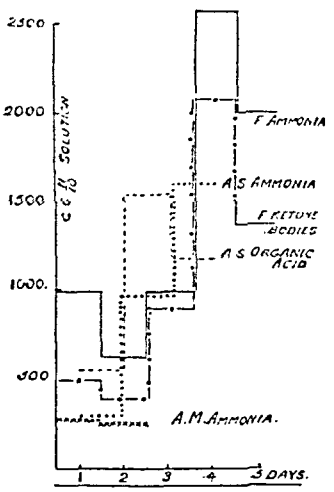

FIG. 2.—Diagram to illustrate the ammonia excretion in two sea-sick persons.

onset of vomiting only six hours after a solid meal taken in comfort and retained; and the small amount of food (mainly carbohydrate) taken and retained after vomiting began should have been sufficient to prevent ketosis. Again, another subject (J. M.) developed ketosis although he retained all but one meal, and the meals taken were mainly carbohydrate.

In Case A. S., which is a fair sample of three cases in which no food was taken, the ketosis was more severe than is usual in starvation in adults. It is true that Folin (1915) found a similar degree in a fat woman who was starved for therapeutic reasons, but that case was quite exceptional, and we have not seen anything comparable in epileptics, nor in a fat woman who was starved to reduce her weight. However, in young children ketosis of this degree may occur (Ross and Josephs, 1924).

In the three cases in which we estimated blood sugar (see Table I) we did not find the rapid fall noted by Oriel: the figures are such as are usual in normal persons before breakfast.

TABLE I

	Blood Sugar	Nitroprusside Reaction
Case A. M.	Per cent.	
At onset of vomiting	0.14	+
Seventeen hours later	0.09	++++
Twenty-seven hours later	0.12	++++
Case J. M.		
At onset of vomiting	0.10	0
Fourteen hours later	0.10	++++
Case J. T.		
Seven hours after onset of vomiting	0.08	++++

It appears, therefore, that carbohydrate starvation alone will not account for the ketosis.

Relation of Ketosis to Symptoms

Ketosis may produce symptoms either owing to the toxicity of the ketone bodies, particularly aceto-acetic acid, or by a disturbance of the acid-base balance such as may be produced by any acid—that is, an acidosis in the strict sense of the word. A good deal is written still about ketosis and "acidosis" in relation to sickness, especially in children. In order to appreciate the effects of ketosis it is well to consider cases occurring in diabetes mellitus. We find here that patients may excrete large quantities for long periods without nausea, vomiting, or mental changes. Joslin mentions a patient who excreted 3 grams of ammonia (=2,000 c.cm. decinormal solution, normal amount) daily for a year, and was able to travel.

It appears, then, that the effects of moderate amounts of ketone bodies are apt to be exaggerated. It might be argued that such patients have gradually become accustomed to large amounts of ketone bodies; we give, therefore, an example (Case F., in Figure 2 and Table II)

TABLE II

Days:	1	2	3	4	5
Case F.					
Ammonia	970	618	930	2,580	1,930
Ketone bodies	500	384	560	2,030	1,380
Case A. M.					
Ammonia	303	290	—	—	—
Ketone bodies	—	136	—	—	—
Case A. S.					
Ammonia	348	930	1,190	—	—
Free acid	334	544	385	—	—
Organic acid	567	1,576	1,184	—	—
Ketone bodies	175	—	—	—	—
Case A. E.					
Ammonia	225 285	—	—	—	—
Free acid	150 275	—	—	—	—
Organic acid	328 537	—	—	—	—
Ketone bodies	— 353	—	—	—	—
Case J. S.					
Ammonia	—	354	—	—	—
Free acid	—	286	—	—	—
Organic acid	—	568	—	—	—
Ketone bodies	—	257	—	—	—

The excretion of ammonia, organic acid, and ketone bodies in one diabetic and four sea-sick subjects; all urinary constituents reckoned in cubic centimetres of decinormal solution. Except in Case A. M. the estimations on the sea-sick subjects began twelve hours after vomiting started. Estimations in Case A. E. made in two twelve-hour periods.

of ketosis of sudden onset without symptoms. This was a young diabetic patient with a short history of illness who had been treated with insulin; the insulin was temporarily stopped and ketosis appeared. Although the ketosis was more severe even than in the subject A. S., there was no nausea or vomiting. Compared with such a case the ketone bodies excreted by A. M. are trivial. When we take into account the fact that nausea and depression may last for several days, and vomiting begin without ketosis, it is impossible to regard ketosis as the cause of the symptoms.

In Case F. we can see the degree of disturbance of acid-base balance that may be expected in such a ketosis of short standing; on the fifth day the plasma bicarbonate had fallen to 49 (normal 55–66); such a degree of acidosis occurs in normal persons after exertion, and is accompanied by no unpleasant sensations—rather the reverse. It is improbable that more than slight disturbance of acid-base balance occurred even in the cases of sea-sickness that were starved. We examined one patient (J. W.), who had vomited repeatedly for two days, but had retained some food. His urine gave a +4 nitroprusside reaction; his plasma *p*H was 7.33 and his plasma bicarbonate was 62; no acidosis had developed in this case.

There is no evidence that acidosis, in the strict sense of the word, will produce vomiting or any other symptoms but hyperpnoea. In fact, the symptoms of sea-sickness suggest far more the collapse seen with alkalosis. The possibility that an alkalosis might be produced either by hyperpnoea or by loss of acid in the vomit is refuted by the fact that all the urines examined were acid. In Case J. W. the plasma chloride was normal (0.63 per cent.), so that there was no evidence of excessive loss of hydrochloric acid by vomiting. Ketosis therefore appears to be an incident in sea-sickness which is not itself the cause of any of the symptoms, but is evidence of some metabolic change which may itself be the cause. What this disturbance is, is not clear; it cannot be frank carbohydrate starvation. There are, however, other conditions in which ketosis appears—for example, alkalosis, pregnancy, and in occasional liver diseases. It is unfortunate that the nitroprusside reaction is not more commonly used in the routine examination of urines, as much knowledge about the occurrence of ketosis might be gained. Children seem particularly prone to ketosis, both in starvation and in fevers. The exact relation of ketosis to cyclic vomiting in children is still unsettled, but the position seems to be very similar to that in sea-sickness.

During a calm voyage we examined the urines of patients who were liable to sea-sickness on rough voyages, but found ketone bodies in none. Also in Case A. M., although ketosis appeared at the onset of vomiting, it was not detected on previous examinations nor during a subsequent voyage when the subject was nauseated and her blood pressure low.

We have therefore found no evidence of a special liability to ketosis in persons subject to sea-sickness.

Conclusions

Ketosis is usual in sea-sickness after vomiting has begun, and occasionally appears earlier.

Ketosis is not the cause of sea-sickness nor of any of the symptoms of sea-sickness.

It may be regarded as evidence of some metabolic disturbance the nature of which is not known.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

A LARGE OCCIPITAL MENINGOCELE

The following case, which presents certain features of interest, seems worthy of record.

The patient, a Hindu female child aged 3 months, was brought to hospital on June 2nd, 1930. There was a tumour, rather larger in size than the child's head, springing from the occipital region, to which it was attached by a thick pedicle. The tumour was fluid and fairly flaccid. The skin covering it was healthy, though beginning to show signs of malnutrition at the most dependent part. Pressure on it did not lead to any signs of increased tension within the skull, nor did it lead to any decrease in the bulk of the tumour. The child was fairly well nourished and had, the parents alleged, increased in weight at a normal rate since birth. The tumour had been present at birth, when it was about the size of an orange, and had steadily increased in size since then; but the general health of the child had been good, and, apart from

its size and weight, the tumour has caused no symptoms. A provisional diagnosis of occipital meningocele, probably with an occluded pedicle, was made, and it was decided to operate.

The operation was performed next day, and presented no difficulty. When the skin and subcutaneous tissues had been incised, a pedicle, about a fingerbreadth in thickness, was seen to issue from the occipital fontanelle. This was incised, and proved to consist of a gelatinous material, surrounded by membrane. No fluid was encountered. The dura was stitched over the opening, and the skin wound closed. On dissecting the removed tumour, it was discovered that the pedicle was filled with a plug of the gelatinous material, the rest of the sac being filled with fluid. Recovery was uneventful, and the patient was discharged on the twelfth day.

In *Tumours, Innocent and Malignant* (seventh edition, p. 741), Sir John Bland-Sutton writes as follows: "There is reason to believe that the pedicle of a cranial meningocele may become obliterated so as to cut off the communication between the cyst and the subdural space. I have never had an opportunity of dissecting a specimen in which this has happened." Is it possible that this plugging of the pedicle with gelatinous material is the first stage in the complete obliteration of the lumen? Unfortunately, there was no laboratory available to which the material could be sent for examination.

Bandah, India.

WHOOPING-COUGH WITH INSPIRATORY STRIDOR

The symptoms occurring in two of the following cases of whooping-cough seem sufficiently unusual to be placed on record.

CASE I

D., aged 32, a medical practitioner, contracted whooping-cough from one of his patients early in February, 1930. The cough was violent, persisted day and night, and was accompanied by vomiting but not by "whoop." The patient was pyrexial for ten days.

Whooping-cough was diagnosed by Dr. Geoffrey Marshall of Guy's Hospital, and a skiagram of the chest revealed no other abnormality. Within a month of onset the cough was more limited to the hours of rest, but was particularly bad first thing in the morning. After an hour's coughing, sneezing of peculiar violence would take its place and the nose would run freely. This would continue for about an hour, or until vomiting ended the morning's bout. For the rest of the day there was no nose-running. The nasal discharge was always watery; never muco-purulent. Two weeks later another symptom developed. As the morning attack was in progress a wheeziness was felt in the throat, and as the other symptoms subsided this became more marked. The patient sounded like a man in an attack of asthma, but the stridor was strictly inspiratory. There was undoubedly a spasmodic condition of the vocal cords, which would last for an hour or more after subsidence of the other symptoms. The nasal and laryngeal symptoms were well marked in June, though the cough was by then insignificant; they have considerably diminished since then and are now only noticed on cold mornings.

CASE II

Miss R., dispenser, aged 29, contracted whooping-cough from Case I, but showed no unusual symptoms.

CASE III

Mrs. S., nurse, aged 58, contracted whooping-cough from Case II in March. She had violent cough, and after a month complained of wheeziness in the throat. She felt "a piece of flesh" in the throat. There were no nasal symptoms, but the laryngeal stridor, which was inspiratory, became well marked and would persist for three or four hours each day It was still present in July. None of the patients was subject to hay fever. Cases I and II had had whooping-cough in childhood. "Whooping" was absent in all three cases.

The interest of the inspiratory laryngeal spasm is in the support it gives to the generally accepted theory that the "whoop" in children is due to an active spasm of the vocal cords. It would be of assistance to know whether these symptoms have been observed in other patients.

London, N.19. I. M. BENJAMIN.

PERFORATIVE DIVERTICULITIS OF THE COLON

In the *British Medical Journal* of January 4th, 1930, Sir W. I. de C. Wheeler reported a fatal case of perforative diverticulitis of the colon. In April last a somewhat similar case, but with a happier termination, was under my observation in the Dunfermline and West Fife Hospital.

A woman, aged 50, had felt vague discomfort in the lower abdomen for fourteen days prior to her admission to hospital on April 5th. On that date, four hours before admission, she was seized with sudden acute pain in the left iliac fossa, radiating to the umbilical region and accompanied by movement of the bowels and by vomiting. On admission she was groaning with pain. Her temperature was 103° F., and her pulse 114. On account of the adiposity of the patient (her weight was 18 st.) it was difficult to localize the seat of trouble, and a perforation of the appendix was diagnosed.

The abdomen was opened by incision through the right rectus muscle; free, non-odorous pus immediately welled up. The appendix was seen to be normal, and on investigating the left iliac region a boggy mass was palpated and delivered into the wound. This was found to be the pelvic colon, heavy with oedema. At about its centre a perforated diverticulum, surrounded by fatty adhesions, was discovered. The diverticulum contained a small faecolith, which was dislodged into the bowel. A left gridiron incision was rapidly made, and the loop bearing the diverticulum was brought through this to the surface. An enterostomy near the terminal ileum was performed, and a local and a suprapubic glass drain were introduced for drainage.

The enterostomy drained well, and there was little post-operative discomfort. The diverticulum discharged faecal matter for some days, and could be easily distinguished. The skin gradually grew over the extruded bowel, and when she was discharged from hospital the left gridiron incision was completely healed. The intention at the time of the operation was to remove later the diverticulum-bearing segment, but this was not carried out, owing to the rapidity with which the extruded bowel became covered over.

Since her discharge the patient has been perfectly well.

J. M. BLACK, M.B., Ch.B., F.R.C.S.Ed.,
Honorary Surgeon, Dunfermline and West Fife Hospital.

HAEMATOMETRA AND HAEMATOSALPINX IN ONE HORN OF A BICORNUATE UTERUS

I read the case reported by Drs. Calverley and Buttery in the *Journal* of March 29th, 1930 (p. 590), with much interest; on account of the great rarity of the condition, I wish to place on record a similar case I operated upon in 1926.

The patient was a young girl, aged 16. Menstruation began ten months before date of admission, and she had menstruated only three times subsequently—two months, six months, and nine months—after the first one. At the first menstruation she had acute pain, and a small irregular swelling appeared in the right iliac fossa, which increased in size at each succeeding period.

On palpation an irregular hard mass was felt in the right iliac fossa; it was about the size of a cricket ball and fairly freely movable, tender on deep pressure, and dull to percussion. Bimanual examination revealed the presence of a tense cystic swelling filling up the posterior fornix, and pushing up the cervix behind and to the left of the symphysis pubis. The uterus could not be differentiated from the swelling.

A median incision was made. There was no free fluid in the peritoneal cavity. The mass was found to consist of

the right tube and right horn of a bicornuate uterus, which were both cystic and separated from each other by a marked constriction. The tube was sausage-shaped and the horn was globular. The mass was adherent to the intestines and the vermiform appendix, and the fimbriated end of the tube was completely closed. The adhesions were carefully separated, appendicectomy was performed, and the tube and right horn were dissected out and removed. Finally, the cut end of the right horn was carefully sutured. The tube and the right horn were found to contain altered blood, and there was free communication between them. The patient made an uneventful recovery, and was discharged cured five weeks after the operation.

Bangalore. S. SUBBA RAO.

Reports of Societies

THE MEDICAL AND SURGICAL USES OF DIATHERMY

A meeting of the Medical Society of London was held on January 26th, with Dr. R. A. YOUNG, president, in the chair, when a discussion took place on "The medical and surgical uses of diathermy."

Dr. E. P. CUMBERBATCH, in opening the discussion, said that diathermy had been practised in this country for a little over twenty years. Its growth during the first decade was very slow, but during the second decade it increased at a rapid rate, and to-day there was hardly a region of the body to which diathermy had not been applied. Diathermy was used for the treatment of certain symptoms such as pain and spasm, for the raising of temperature of parts pathologically subnormal, for the reduction of blood pressure which was pathologically high, for aiding resolution of inflammation, for helping the tissues to free themselves from infection, and for elevating the temperature of the entire body, producing what was known in America as "therapeutic fever." Dealing with different specialties in turn, Dr. Cumberbatch first spoke of the uses of diathermy in gynaecology. Diathermy had made its most striking advances in the treatment of certain diseases peculiar to women. By means of diathermy it was possible to raise the temperature of the urethra and of the cervix to 114° F., or perhaps one degree higher. As a result, all clinical signs and symptoms of infection of those parts disappeared. The gonococcus disappeared in 90 per cent. of the cases, the *Streptococcus haemolyticus* in about 80 per cent. In order to raise the temperature of the parts mentioned to 114° or 115° it was necessary to adopt a special technique. The method used as a standard in his own department was devised by his colleague Dr. C. A. Robinson. It was sometimes stated that any region of the body could be heated to any temperature by diathermy, but that was not the case. In the depths of the vascular parts, and in the pelvis, abdomen, or thorax, the temperature could be raised only by a slight degree. In regard to the tubes and ovaries it was possible by means of diathermy to effect a fairly high degree of "therapeutic fever," though not to obtain the high temperatures possible in the urethra and cervix. Dysmenorrhoea due to minor degrees of infection of the tubes could always, in his experience, be brought to an end by intrapelvic diathermy. The application of diathermy to the interior of the pelvis had some influence on the ovarian hormones. If the cessation of menstruation was premature in women, it was a common occurrence for pelvic diathermy to start it again even after a number of years. The application of diathermy to the interior of the pelvis had the effect of bringing climacteric bleeding to a stop and of diminishing or abolishing the symptoms peculiar to the change of life. Dr. Robinson had treated a number of cases of puerperal fever at the West Middlesex Hospital, and had been able to bring the fever to an end in thirty-three cases out of thirty-nine. Passing to conditions affecting men, Dr. Cumberbatch said that in gonococcal infections of the epididymis diathermy was almost invariably effective. Applied to the prostate gland by way of a rectal electrode, a powerful effect was produced on gonococcal prostatitis and vesiculitis. The greatest difficulty he had found was in cases of prostatitis which gave a history of gonorrhoea in which there was a persistent gleet; in the majority of these cases he had not been able to obtain complete results. Recently he had had three or four cases of men aged 55 to 65 who were beginning to get symptoms of obstruction as a result of enlargement of the prostate, and these cases had received benefit by diathermy. Their symptoms had disappeared, and so far they had kept well. With regard to the joints, gonococcal arthritis could be very satisfactorily treated by applying diathermy, not to the joint, but to the prostate and vesicles in men, and to the cervix in women, and in almost all the cases the effect of the treatment was to abolish the pain, to increase the range of movement, and to diminish the swelling. In women suffering from multiple arthritis it was very common to find an infection of the cervix which was non-gonococcal. The application of diathermy to the cervix brought the arthritis to an end in about 75 per cent. of cases. He believed also that it was possible for a non-gonococcal prostatitis to be responsible for a secondary arthritis in men, and in a few cases the application of diathermy to the prostate had cleared up the joints. Women just before or just after the climacteric tended to put on weight and to get pain in the knees and wrists, and on examination pads of tissue resembling fat were found in the neighbourhood of the knees and the upper arms. If these cases were treated by general pelvic diathermy the pain in the joints disappeared, the swellings diminished, and the patient lost weight. He believed the arthritis in such cases was due, not to infection, but to disturbance of the endocrine function of the ovaries. He suggested, also, that there was a type of arthritis in elderly men which was analogous to the climacteric form in women. With regard to the circulatory system, diathermy had been recommended by some authorities for the treatment of hyperpiesis. His own experience showed that cases which had been under general medical treatment and had been left with certain symptoms could be benefited. Diathermy did not lower the blood pressure permanently, though the first applications of the treatment produced a temporary diminution. If, however, the blood pressure was very high—say, 250 to 260 mm. Hg—there appeared to be a much longer duration of the lowered pressure after treatment by diathermy. He had had no personal experience of angina pectoris where the spasms were agonizing and sudden, though diathermy was recommended in some of these cases. His work had been confined to cases of "angina without agony"; such did not respond particularly well. In intermittent claudication diathermy was disappointing. The most he could claim for it was relief of the pain which was sometimes present. In lobar pneumonia many cases had been treated by this method in the United States. In this country opinions were divided, but in the West Middlesex Hospital one room had been set apart for treatment of lobar pneumonia by diathermy. He had a number of derelict asthma cases which had left other departments of the hospital, and the patients said they felt better after diathermy, the attacks being less severe and less frequent. He also spoke of astonishingly successful results in mucous colitis. In diseases of the skin, surgical diathermy was strongly to be recommended. Diathermic coagulation in which the heat was concentrated in the

mass it was desired to destroy was very useful for papilloma of the skin, flat warts and naevi, telangiectases, and pigmented areas. He had used it also for lupus vulgaris. With regard to diseases of the eye, he had treated only two or three cases of gonorrhoeal iritis, and there was a quick relief of the pain. In the treatment of diseases of the upper air passages surgical diathermy had produced some of its most remarkable results. He wished to hear the opinions of members on the treatment of enlarged tonsils by diathermy. The public had heard of this method of treating enlarged tonsils and were rather anxious to have it in preference to the ordinary operation.

Mr. SAMPSON HANDLEY spoke of diathermy as used in cancer surgery. Diathermy had the property, he said, of sterilizing the tissues to a considerable depth. In cancer surgery one of the great difficulties was the presence of secondary infections around the primary growth. Therefore it seemed likely that the diathermic needle had a great advantage over the scalpel, which latter could not pretend to any such antiseptic action. He had come to the conclusion that over large fields of surgery the diathermic needle was definitely superior to the knife, and he believed that in two or three years a large proportion of surgical operations would be done by diathermy. He had used the cutting current and a needle only, and those who had not seen the method would be astonished at the ease with which the tissues faded away at the approach of the needle without employing mechanical pressure. Ten years ago he began to use diathermy in surgery, at first for inoperable cases of breast cancer. He was surprised at the way in which the wounds healed; even in old patients the healing seemed unusually rapid and also painless. He was encouraged, therefore, to apply the method to the treatment of operable breast cancer, using the needle as he would use the knife, though being careful not to go near the axilla, with its large vessels, for fear of puncturing them. Since 1927 he had used diathermy almost exclusively for operating on breast cancer. It did not interfere with primary union, and the wound could be sutured completely as after a cutting operation. If the machine was working efficiently the method had a slight advantage over the knife in respect of rapidity. One advantage of the diathermic needle was that it sterilized the wound surface, and therefore the risk of transferring cancer cells from one part of the wound to another was minimized. Another advantage was the avoidance of the risk of chill. One of the difficulties of the breast operation by the knife was to keep the flaps warm after they were cut. With diathermy the flaps, as one could feel through the glove, when first cut were warmer than normal. Bleeding also was much lessened, and the number of vessels to be tied was reduced. It was better, however, to tie a vessel than to apply a terminal too persistently to a bleeding point, and that applied especially to vessels which lay near the pleura. Shock was generally absent, and that was a point which deserved the attention of the physiologists. Among the slight disadvantages of surgical diathermy was the fact that ether could not be used as an anaesthetic; also, if the needle was used to divide the skin, the skin edges at the end of seven or ten days might become red and suggest incipient skin infection, but these symptoms could be dealt with by spraying the wound daily with antistaphylococcic virus. Perhaps the most serious danger was that of overheating a long thin flap. Great care should be taken not to transmit too great a current through the base of the flap, so as to run the risk of thrombosing the vessels which nourished it. He had tried during the last three years to extend the scope of diathermic operations within the abdomen, and had found that they had great technical advantages in the operation of gastrectomy. It quite altered the aspect of the first few days of convalescence. Shock was largely eliminated, and the patient did not suffer from the rapid pulse and collapsed condition which was common after knife operations. The technique he used for gastrectomy was to open the abdomen by the diathermic needle, and then to use diathermy for dividing the stomach and the duodenum and the omentum, after applying clamps in the usual way. If the needle were allowed to touch the intestine at any point there would be perforation, but that danger could be avoided by care and technique.

Dr. F. D. HOWITT said that diathermy had three main fields: surgical diathermy, where the current was concentrated at the active electrode to such a point as to produce destruction; medical diathermy, which was used when heat was required internally; and a third form in which the heating was sufficient to sterilize the tissues without producing destruction. With regard to cervical erosion and sepsis, he had used Dr. Cumberbatch's technique with excellent results. Diathermy was valuable in the treatment of anal fissure and spasm. It was useful also in iridocyclitis, where the trouble of giving heat by ordinary methods, such as conduction or radiation, was that it was quickly carried away by superficial circulation, and penetrated only to a slight degree into depth. By diathermy a large concentration of heat reached the inside of the orbit. Dr. Howitt showed an instrument designed to attack the tonsil by surgical diathermy.

Mr. C. HAMBLEN THOMAS said that he had found diathermy a definite aid in the treatment of ear conditions, though, unfortunately, the relief appeared to be only temporary. With regard to the tonsils, he thought it would be difficult to sterilize the tonsil which had a deep infection at the base near the capsule. Mr. W. IBBOTSON mentioned that he had removed a large cancerous mass in the pharynx by diathermy, with extremely rapid and painless healing. Mr. MORTIMER WOOLF was sure that the results of diathermy in breast cancer were infinitely superior to those obtained with the knife. A finer needle should be used for the skin than for dividing the deeper tissues, also a rather more powerful current. After the skin was divided, the current should be always reduced. An important point, only learned with practice, was to move the needle quickly, yet not too quickly. If the proper speed was attained, the skin divided just as with the knife. Sir JAMES DUNDAS-GRANT asked as to the degree of freedom from recurrence; the recurrence in some cases had disappointed him. Mr. PHILIP TURNER gave instances of two cases in which diathermy had been tried, one seventeen and the other eighteen years ago. One had been treated for an ulceration involving one side of the lip and the nose, at first assumed to be lupus, and treated as such, but later becoming definitely malignant. The other was a case of advanced gland tuberculosis which had broken down. He saw both these patients when they came up for other conditions recently, and the diathermy treatment had proved effective and permanent.

Dr. CUMBERBATCH, in reply, said that Mr. Sampson Handley must have been the first to attempt the use of a cutting current for the abdominal organs. He detected some confusion of nomenclature in Mr. Handley's mention of the "diathermic knife." If a scalpel was used as an active electrode it was a true diathermic knife, but the reference to the needle and the cutting current as a "knife" was rather to be deprecated. The question of the use of diathermy in catarrhal deafness had been raised; he himself had not got any striking results. Theoretically, the action of diathermy was to raise the temperature of the middle ear, and where there was inflammation, the heat would assist its resolution.

THE RADIOLOGICAL RENAL OUTLINE

At a meeting of the Section of Urology of the Royal Society of Medicine on January 22nd, with Mr. S. G. MACDONALD in the chair, a discussion on the significance of the radiological renal outline was opened by Dr. S. GILBERT SCOTT.

Dr. Gilbert Scott said that the radiological examination of the urinary tract could not be considered complete unless the renal outlines were clearly demonstrated. He had read a paper on this subject at the Annual Meeting of the British Medical Association in Cambridge in 1920, but at that time there were very few radiologists who were capable of showing the outline of the kidneys. The technical side of radiology since then had advanced rapidly, and the difficulty of demonstrating the renal outline no longer existed. Even the suprarenal gland could now be shown, and this might possibly be of some diagnostic value. It was obvious, however, to the more experienced radiologist that diagnostic accuracy or skill had not reached the same high level as radiological technique. This was quite understandable when it was remembered that anyone could buy an up-to-date apparatus and after half a day's instruction turn out first-class radiograms. The primary object of the radiologist should be to extract every atom of accurate information from his examination, and pass the findings on in a clear and concise form to those concerned, his films being used to demonstrate and record the evidence on which he based his diagnosis. In the *x*-ray examination of the kidney a soft tissue organ had to be shown against a background of soft tissue—the back muscles—and faulty preparation or slight movement would make the outline of the kidney impossible. Two essentials were the clearance of the bowel and efficient abdominal compression, for which latter purpose he recommended a "sugar-loaf" compressor, something like a football, designed to apply pressure under the costal margin and lift it up. If it could be definitely stated that the patient had both kidneys apparently normal in position and size, containing nothing in the way of calculi, it would be a point of considerable value. Dr. Scott illustrated three variations from the normal shape of the kidney, which he called the globular, the elongated, and the lobular. The degree of excursion of the kidney on respiration differed widely as between patients; in one it might be 1 inch and in another 3 inches. It was not always easy to decide when a kidney was enlarged. Uniform enlargement was met with in hypertrophy, hydronephrosis, pyonephrosis, and new growth. Finally Dr. Scott referred to the value of the renal outline when opacities were present, and he described his own method, which had proved of great practical value at the London Hospital during the last ten years, of determining whether an opacity was intra-renal or extrarenal. This method was based on the assumption that any opacity located within the limits of the kidney shadow must be of renal origin if the respiratory excursion was equal to that of the kidney in direction and extent. He called this method "renal localization," and showed a cinematograph diagram illustrating the respective movements of a related and an unrelated shadow and of the kidney outline during the phases of respiration.

Mr. JOHN EVERIDGE said that the value of the method of observing the relative mobility of the kidney and of an opacity was rather diminished because, in a great number of such cases, where there was a shadow, the kidney was a fixed kidney, with considerable perinephritis. The method, he believed, could not be so complete and satisfying as pyelography, without which he never thought of attacking renal calculi. Mr. F. A. G. JEANS considered that the surgeon who went against the radiographer's opinion as to the presence or absence of stone was taking a great responsibility. It was true that sometimes the radiologist might be in error, but sometimes also the mistake might lie with the surgeon, who failed to find the stone which was actually present and radiographically demonstrated.

Dr. E. J. H. ROTH thought it unjustifiable to suppose that the movement of a doubtful shadow necessarily denoted that it lay within the renal substance. There were a number of other shadows which moved with the kidney—that of a calcified gland adherent to the kidney, for example—whilst, on the other hand, a floating calculus lying in the renal pelvis might remain stationary as the kidney moved downwards. The lateral radiogram with pyelography and the stereoscope offered the most complete method of localizing a doubtful shadow in the renal areas. The most useful method of preparation was to give the patient a vegetable laxative on two successive evenings before the examination.

Mr. E. W. RICHES said that the preparation was very important. Many radiograms were entirely spoilt by the presence of gas in the bowel. He thought that better radiograms were generally secured in the case of out-patients than in the case of in-patients, probably because the former were out and about, not lying in bed. Matters might be improved by giving the patient charcoal the night before examination, but that did not always work. Mr. CYRIL NITCH had seen three cases in which a pigmented mole in the back had thrown a shadow in the renal area which at first was mistaken for a possible stone. He believed that nothing equalled the stereoscopic radiograph after the passing of an opaque bougie. Most of the shadows seen were in front of the kidney, and the stereoscopic position would localize them with accuracy. Mr. CLIFFORD MORSON said that there was danger of the radiologist forgetting, in his absorption in the radiological picture, the clinical one. Accurate diagnosis in the long run depended on clinical skill. Mr. WINSBURY WHITE commented on Dr. Scott's remark that enlarged kidney resulted from hydronephrosis, among other things, and mentioned two cases of this condition in which the kidney was actually a little smaller than normal. It would certainly have been impossible to diagnose these cases by the plain radiograph as in any way pathological. He diagnosed them by pyelography; when removing the kidney he found that the ureter had become obstructed by blood vessels, and this added obstruction had no doubt caused a considerable degree of atrophy without thinning the renal substance in the way customarily found. Mr. JOCELYN SWAN had found the greatest value in the stereoscopic *x*-ray picture, and pleaded for greater co-operation between the surgeon and the radiologist. He did not think absolute reliance could be placed on the shadow which moved with the respiratory excursion. Mr. S. G. MACDONALD referred to the general question of the relation between the radiologist and the surgeon. Personally he always discussed the plates with the radiologist, but, after all, the urologist had been specially trained in the *x*-ray appearances in these cases.

Dr. GILBERT SCOTT, in reply, said that he did not claim for his renal localization method that it replaced pyelography in cases in which that method was indicated, but it was a method available for ordinary everyday work, without the trouble and disturbance to the patient which pyelography involved. With regard to preparation for examination, he relied chiefly on castor oil given twenty-four hours previously, carbohydrates being excluded from the diet. This seemed to result in less gas in the intestine.

TREATMENT OF ECZEMA

The meeting of the Chelsea Clinical Society on January 20th was devoted to a discussion on the treatment of eczema. Dr. F. J. McCANN presided.

Dr. HENRY MACCORMAC said that there were two great groups of skin diseases, the parasitic and the non-parasitic. In the former the cause was known; in the latter, of which eczema was perhaps the best example, the cause was not known, and only the symptoms were treated. There was not the disadvantage in the treatment of symptoms that was found in other branches of medicine, because there was nothing behind the skin condition, and if the eruption could be removed, the patient was perfectly well. He conceived that eczema was due to two separate things, an internal cause and an external one, which were complementary. He believed it to be a specific condition, due to some diathesis. Treatment must be general and local. The question of sensitization had to be considered in connexion with eczema. The patient might be sensitive to a certain food or other material, and when the antigen was liberated a reaction occurred which produced the eczema. He did not think that that should be called a specific reaction. An egg which in one person caused eczema might in another cause urticaria or asthma. The reaction belonged to the individual, not to the agent. But if the agent for a particular individual could be cut out, one of the things had been removed which interfered with health, and the eczema was likely to disappear. It was important at the beginning to examine the case generally, and to see if sensitization to any particular agent could be discovered. One of the most valuable measures for desensitizing was the intravenous administration of thiosulphate; 0.6 gram dissolved in 10 c.cm. of distilled water could be given every third day. But while general treatment was important, the local treatment was also necessary, eczema being very largely due to external causes. He had for his own purpose arranged his remedies in a scale, beginning with lotions, and then proceeding to a liniment or cream, a paste, and finally ointment. The eruptive process was not always present in the same degree in different parts of the body. Local treatment might be designed to fit the different stages of the eruption. In acute cases the old remedy, glycerin and lead, he had found to be useful. The part was rubbed with lint soaked in this substance, and kept constantly wet for twenty-four hours, after which time the acute inflammation would have subsided, and the itching diminished to a considerable extent. In the second stage the condition demanded something of an oily nature. His choice was calamine liniment in which, besides olive oil, there was lime water, which evaporated. After a time it would be felt that a change must be made again, and, as it might not be desirable yet to use an ointment, a compromise could be effected with a paste. The incorporation of a large amount of powder in the paste allowed the exudation present in the eczema to make its way to the surface, and the condition was not shut in as it was by an ointment. In the final stage the condition might become sluggish and demand some stimulating application and vigorous treatment. Probably there was nothing so valuable at this stage as coal tar, which could be applied directly to the part, or, even better, used in the form of an ointment. One gram of crude coal tar in an ounce of Lassar's paste might be applied directly to the part. If one had an *x*-ray apparatus, this was the time to give a small dose of *x* rays, which relieved irritation and promoted healing. Almost every patient asked about diet, but he believed there was no need to diet the patient specially, as long as the dietary was kept within reasonable bounds. The most distressing feature of eczema was the itching, which was worse than the pain, and more difficult to relieve. The local treatment would do something to mitigate it; in extreme cases even morphine might have to be given. But most of the agents recommended for the relief of itching would make the eruption worse. Aspirin was one of many drugs employed with some success, but the problem was a very difficult one.

Dr. H. C. G. SEMON remarked that eczema was supposed, nowadays, to be a dysfunction of the epidermal cell. It was the epidermis rather than any other part of the body which was involved. He thought that sodium thiosulphate was of more service in seborrhoeic eczema than in the ordinary varieties. Coal tar was undoubtedly the best local application available, but it should never be used if there was the least sign of pus because it always accentuated sepsis. If the patient was stout some good result would be obtained from a restricted diet. Dr. R. H. STEVENS mentioned a patient who had an urticarial eruption affecting the nose and malar region, which was traced to the fact that she had been wearing new glasses of imitation tortoise-shell, and had become sensitized to some composition used in the manufacture of the frame.

Dr. P. MONTAGUE SMITH said that he had seen many cases of eczema occur in women through the wearing of cheap furs. The eczema produced was of a painful and chronic variety. The primary thing in all treatments must be to make the patient a healthy person generally. One could not regard eczema as entirely a disease of the skin without taking into consideration the general health. Some measures must be taken, in the case of fat people, to get rid of excessive adipose tissue. One of the most difficult forms of eczema to treat was that which occurred in very small children, associated, perhaps, with intestinal disorder. Dr. L. D. BAILEY said he had found that a lamp rich in both the long ultra-violet and the red rays was useful for the chronic lesions. Dr. ELLIOTT referred to the hereditary factor.

The PRESIDENT said that his experience of eczema was limited to cases at and after the menopause. He had seen such cases improve dramatically after being given thyroid and put on suitable diet. In his view diet was a very important factor in eczema. The skin might be regarded as the barometer of the intestinal condition. By a complete change of diet the chemistry of the intestinal canal was altered and the skin manifestations disappeared.

BACTERIOLOGY AND THE CLINICIAN

The Liverpool Medical Institution held a meeting on January 15th, when Dr. J. D. ALLAN GRAY read a paper on "Recent bacteriological research which is of value to the clinician." He began by saying that recent work had been characterized by the accumulation of much detailed information. The ideal of prevention in infectious disease was now attainable in small-pox, enterica, cholera, plague, typhus, tetanus, scarlatina, and diphtheria. A brief description was given of the Dick and Schick tests and of the active immunization against, and treatment of, scarlatina and diphtheria. After explaining bacterial variation, the terms "H" and "O," and the use of the products of the Standards Laboratory, Dr. Gray outlined the theories of the action of the bacteriophage, discussing also its therapeutic uses. He made a protest against the indiscriminate use of vaccines. Immunologically the procedure was irrational, and further difficulties were due to the specificity of the immunity produced, our lack of knowledge of the intricate mechanism of immunity, the variation in response in different species and in different individuals, and the frequent failure to determine the primary organism in cases of mixed infection. There was no method of predicting the results of the administration of a vaccine. The speaker concluded with a plea

for sympathy with the research worker. Work which had at first appeared unduly academic had often proved eventually of the utmost practical value.

In the discussion which followed, Professor J. H. DIBLE congratulated Dr. Gray upon a comprehensive survey of a number of subjects especially interesting to the practitioner. With regard to vaccines, he thought that many persons must have had a few dramatic results and a great many disappointments, and he admired Dr. Gray's courageous attack upon this form of treatment. He pointed out that the confusion depending upon bacterial variation was at the present time largely resolved. Pure "O" infections in the typhoid group were not common in this country, although apparently frequent in South Africa. Much of the confusion was due to the introduction of the so-called Oxford "Standard" emulsions, which had been imposed by authority upon rather mistrustful pathologists during the war and had since entered the field of civil practice. These contained chiefly "H" antigen, and introduced a consequent complication which did not exist in the older method of employing living cultures. The activity of the bacteriophage was one of intense interest since it constituted a new phenomenon which he, among others, considered closely allied to the virus diseases of man and animals. Investigation of these was difficult, and it might well be that information obtained by the study of the bacteriophage could be extended to their elucidation. In conclusion, Professor Dible said that no immunity appeared so successful as that conveyed by a living virus, however attenuated it might be. This was seen in anthrax and in small-pox, whilst further evidence of it was forthcoming in the case of the virus diseases. Here it appeared that dead viruses were incapable of producing immunity, or only gave rise to such an incomplete degree as to escape detection.

Dr. CRONIN LOWE referred to the more satisfactory results with vaccine therapy in those cases in which the preparation employed contained organisms shown to be pathogenic to the patient concerned, by means of the pathogen-selective culture method. By such means a definite attempt was made to develop a more rational, and purer, type of vaccine treatment than was employed by simply utilizing all the organisms isolated from the specimens of any case. Not only did this apply to many forms of clinical infection of unknown origin, but particularly to a very large group of infective arthritic and fibrositic cases, and to the chronic catarrhal infections from which evidence was also obtained. The patient became not only effectively immunized against recurrent attacks, but, later on, bacteriological investigation gave evidence of a reduction in catarrhal carrier importance.

Dr. C. O. STALLYBRASS said that investigation carried out at an institution where diphtheria was formerly prevalent and carriers were numerous, and where immunization had been carried out for five years, had shown a complete absence of carriers of virulent diphtheria bacilli, although the disease was prevalent in the city and numerous carriers were found in the day schools.

SENILITY AND REJUVENATION

At a meeting of the Hunterian Society held in Apothecaries' Hall on January 19th, with the president, Professor SHEEN, in the chair, Dr. ARNOLD LORAND of Carlsbad delivered the Hunterian Lecture on "The problem of rejuvenation." The lecturer called attention to the frequency of achlorhydria, anaemia, and degenerative changes in the ductless glands as commonly accompanying senility, and said that intestinal stasis and excessive proliferation of bacteria in the alimentary canal, even in the duodenum and stomach, might follow a reduction in the acidity of the gastric juice and induce anaemia and other morbid conditions. Rejuvenation might often be achieved by attention to diet; fats having a high melting point, such as mutton fat, were difficult to digest, and should be replaced in the dietary by olive oil. Carbohydrates were best given in the form of fresh fruit and vegetables; bananas had been found particularly valuable in this connexion. A milk diet tended to check intestinal putrefaction; it was significant that Holland and New Zealand had a low mortality rate, and both these countries were noted for dairy produce. Constipation should be treated by natural remedies, such as cellulose, rather than by drugs; colonic lavage was often very beneficial. Pavlov's observations had shown the importance of food being attractively prepared; badly cooked food failed to elicit an adequate digestive juice. The speaker suggested that no marriage licence should be issued unless the bride produced a certificate of proficiency in cookery. Surgical operations, such as those of Voronoff and Steinach, gave good results in restoring sexual activity to senile animals, but these operations seldom produced any lasting benefit in man. Sexual impotence in man was often due to neurosis, and might be successfully treated by diet; among the natives of Guatemala nervous disorders were rare, and impotence practically unknown; the diet consisted mainly of beans and rice. It was idle to expect to transform an old man into a young man, but youth could often be prolonged by attention to hygiene; it was encouraging to find that the general public now took a greater interest in the rules of health.

CHRONIC APPENDICITIS

At the December meeting of the Sheffield Medico-Chirurgical Society, presided over by Professor GRAHAM SIMPSON, Mr. J. C. ANDERSON read a paper on chronic appendicitis. Dealing with the production of the symptoms and signs of chronic appendicitis without regard to the pathological processes, Mr. Anderson said that a local lesion in the alimentary tract was apt to set up distant reflex motor and secretory disturbances. Thus, ileo-caecal disease could produce gastric as well as ileo-caecal symptoms. The wall of the intestine was insensitive to ordinary pain-producing stimuli, but excessive muscular contraction, resulting from obstruction or from irritants, was manifested by referred pain in the abdominal wall. Ileo-caecal and appendicular colic were felt at the level of the umbilicus, but were unaccompanied by symptoms or physical signs. Inflammation of the parietal peritoneum, however, caused local pain, tenderness, and muscular resistance. The symptoms and signs of appendicitis depended upon mechanical or inflammatory factors. The abnormalities of the appendix which led to symptoms of mechanical origin were immobility, kinking, strictures, and concretions. In these cases pain might be felt in the ileo-caecal region or there might be an irregular type of dyspepsia; nausea and vomiting were also common symptoms, occurring sometimes without other local or general signs. When the appendix was inflamed, motor disturbances similar to the above might happen, but when the parietal peritoneum was involved, there were both local and general symptoms. In each mechanical and inflammatory symptom-group, *x*-ray examination might show reflex motor disturbances of the stomach as well as ileo-caecal distortion. Pain in the appendix, resulting from mechanical factors or occurring between inflammatory attacks, had to be recognized from symptoms alone, as physical signs were present only when the inflammatory process was active. If the predominating symptom was colic some of the causes enumerated above should be proved on exposure of the appendix. During an inflammatory attack, signs of inflammation would be found; but at operation the evidence might be slight if laparotomy was done at a quiescent period. Mr. Anderson stressed the importance of the evidence afforded by enlarged ileo-caecal glands. Finally, he surveyed briefly the question of differential diagnosis of right-sided abdominal pain, colic, and dyspepsia due to other causes. Phthisis might be associated with umbilical colic resulting from tuberculous enteritis, and possibly with right-sided abdominal symptoms originating in a right basal pleurisy.

Reviews

THE STUDY OF RHEUMATISM

In making their contribution[1] to the Recent Advances Series, which has proved so useful to the whole medical profession, Drs. POYNTON and SCHLESINGER undertook a very difficult task. There is no doubt that they faced it with courage and have produced a most readable book, full of interesting and stimulating material. That no very definite conclusions can be drawn is no fault of theirs, but demonstrates the fact that rheumatism still remains an unsolved problem.

The first and major part of the book is devoted to "acute rheumatism," comprising rheumatic fever and the subacute rheumatic infection of childhood. This section is an admirable piece of work; it shows that, though there is still a great deal of divergence of opinion, research is being conducted along so many lines that a successful issue is almost in sight; and we may hope that before long the vexed questions of etiology and rational preventive treatment will be solved. A good deal of space is given to the question of predisposing causes, especially in relation to climate and damp houses. The relationships of streptococcal infection, tonsillitis, and allergic reaction to the clinical manifestations of rheumatism are all dealt with adequately and clearly. In the section devoted to treatment the chapter on nirvanol and its peculiar reactions is of special interest, and we note a timely warning against reckless administration of this drug. The establishment and administration of rheumatic convalescent schools are described, and attention is drawn to the lamentable shortage of these desirable institutions in this country.

In the section on chronic rheumatism the authors have been less happy. Here they give a catalogue of very conflicting views on pathology, etiology, and treatment, without succeeding in drawing these together into any coherent scheme. They do not really distinguish between rheumatoid arthritis and osteo-arthritis, and we find no mention of fibrositis and muscular rheumatism. They point out, however, the fallacies in the attitude of those, on the one hand, who regard chronic rheumatic diseases as entirely due to focal infection, and of those, on the other hand, who put them all down to metabolic disorder, and they insist on a broad view which will take into consideration all the many factors that go to make up the rheumatic syndrome. They do service in pointing out that the prognosis in these diseases, distressing and prolonged as they are, is by no means hopeless; most wisely they urge the physician to treat the patient and not the disease, and to eschew the current therapeutic fad in vaccine, protein shock, or diet. The divergencies of view on vaccines and diets, exposed in the separate chapters devoted to these subjects, have to be read to be believed, and with such uncertainties in the minds of the profession it is no wonder that the rheumatic diseases are the happy hunting ground of the quacks. Nevertheless, it is doubtful if things are quite so chaotic as this section would seem to indicate, and those with prolonged experience in the treatment of these diseases have a clearer idea of what they are treating and how to do it than would be gathered from the study of the present volume. Dr. F. Howitt contributes a final descriptive chapter on the various forms of physiotherapy, and rightly points out that experience in the art of prescribing these measures is just as important here as in other branches of therapeutics.

[1] *Recent Advances in the Study of Rheumatism.* By Frederic John Poynton, M.D., F.R.C.P., and Bernard Schlesinger, M.D., M.R.C.P. London: J. and A. Churchill. 1930. (Pp. viii + 313; 25 figures. 12s. 6d.)

CLASSIFICATION OF CULTURE MEDIA

A classified list of the large number of media which have been used for the cultivation of micro-organisms, pathogenic and otherwise, has been prepared by LEVINE and SCHOENLEIN of Iowa. Their book[2] was written at the instigation of the Society of American Bacteriologists, and financed by the Digestive Ferments Company of Detroit; this combination of science and commerce has resulted in the appearance of a volume *sui generis*. The long catalogue of media here detailed, some 7,000 in number, bears witness to the industry devoted to their inventing, and to the labour that must have been expended in collecting and classifying them. The media are grouped and subgrouped according to their composition; in each case are recorded the ingredients, the mode of preparation, and the purpose for which the particular medium has been recommended. Both the text and the several indexes illustrate how completely the sifting and dissecting of original references has been carried out; for this reason alone the book has a real value, since, without its help, the search among numerous publications in several languages over many years must consume a great deal of time. But the practising medical bacteriologist will complain of redundancy, because, while a great number of media are described for the cultivation of a single bacterial species, he is given no guidance on how and why to choose any one rather than another; there is, in fact, some risk of his being perplexed by an encumbrance of wealth. For example, the index refers to over 100 pages, scattered throughout the book, on the preparation of media which have been recommended for the tubercle bacillus; the beginner is thus left wondering and puzzled, while the expert will ignore the multiplicity of suggestions and hold fast to what his individual experience has led him to approve. The bringing together of so many different experiences with media should render it possible, however, when the advantages of each constituent have been assessed, to furnish an ideal medium which will suit the requirements of each bacterium. It would be a truly constructive work if some authoritative body would define the essential features of such an ideal culture medium, for, if a universal medium is beyond the scope of the practicable, there must be an optimum constitution for each purpose.

ABDOMINAL DIAGNOSIS

A rose by any other name would smell as sweet, and it matters little that MONDOR'S fascinating book has found publication as the "Abdomen" section of a series entitled "Urgent Diagnosis."[3] If "urgency" be the essential, then this volume is laid open to serious criticism, but if the emphasis be on "diagnosis," then its discursive pages need fear no very fierce onslaught. Is it not delightful to have perforation of the appendix illuminated by the very drawing sent by Cornil, after the necropsy on Gambetta, to Lannelongue, to show him that his diagnosis had been right, that his wish to operate was justified, and that he might well have saved his patient—who died in 1882 of acute appendicitis—had not Charcot, Verneuil, Trélat, Brouardel, Cornil, and Siredy withstood him? How pleasant to find twenty-five pages devoted to a thorough *exposé* of perforations of Meckel's diverticulum. How instructive to find a long series of radiographs of acute intestinal obstruction of various types;

[2] *A Compilation of Culture Media for the Cultivation of Micro-organisms.* By Max Levine, Ph.D., and H. W. Schoenlein, M.S. Monographs on Systematic Bacteriology. London: Baillière, Tindall and Cox, 1930. (Pp. xvi + 969. 67s. 6d. net).

[3] *Diagnostics Urgents: Abdomen.* Par H. Mondor. Paris: Masson et Cie. 1930. (Pp. x + 846; 245 figures. 145 fr.)

of perforations of peptic ulcers with free gas in the peritoneum playing characteristic tricks; of acute intussusceptions, reducible and irreducible, by the opaque enema. To many, these pictures will be new, and perhaps instructive, though there may be a lingering doubt as to the welfare of the patients who are submitted to radiography when acutely ill. We note with pleasure that the author is far better versed in, and far more ready than most of his countrymen to acknowledge indebtedness to, English-speaking authors.

Like nearly all books that profess to deal with "diagnosis," the actual matter is very largely concerned, not with signs and symptoms, though these are prominently placed, even if a little scattered, but with classification and description of pathological states and their ways of happening. This is of course essential if interpretation of clinical pictures is to be precise. There is a wealth of illustrative cases, and not the least useful among them are the many in which the original diagnosis was wrong. Indeed the further one reads in these pages, as perhaps the further one progresses in actual experience, the more difficult does accuracy in exact diagnosis appear. Even statistics, of which there are many here, culled from diverse sources, prompt or confirm the notion that diagnosis rests on little more than probability. The author acknowledges no such pessimism. The section, for instance, on the diagnosis of mesenteric thrombosis, although it recounts wide differences of informed opinion upon the prevalence of almost any and every symptom, ends with the firm statement that the diagnosis can be and ought to be made, relying on (1) signs of incomplete obstruction, (2) an ill-defined diffuse, dull tumour, (3) signs of internal haemorrhage with early collapse. Dr. Mondor lays repeated stress on the absence of tympanites and the presence of an area of dullness. He has had such a case and made the diagnosis. When he meets this syndrome again he will repeat his success. But what of the surgeons who have seen only those cases in which distension of coils above those affected has obscured the dullness of the tumour?

However experienced and well-informed the reader, a dip into this lucky-bag will always result in some prize. Certainly a book worth keeping.

THE SPIRIT OF CHEMISTRY

The *Spirit of Chemistry*,[1] by ALEXANDER FINDLAY, is in some sort a history of chemistry, but that is not quite what the author set out to produce. It might be better to describe it as a history of the development of chemical thought and conception: yet it is more than that. There seems to be no better clue to its contents than the thought comprised in the title itself, as it appears to be the fittest expression of the author's incentive to write the book. His stated purpose is to provide for the many university students who take a course in chemistry as an element of general culture rather than as a part of their professional or technical training. The treatment is thus necessarily different from that of a work intended for the plain layman. Yet it is not too difficult for the layman who has a moderate acquaintance with the nomenclature of chemistry, and it may be commended to the layman who is interested in chemistry as well as to those for whom it was more expressly written.

The general theme of the book is to describe and explain the fundamental experiments which form the foundations and superstructure of the great storied edifice of chemistry, and to illustrate the more important application of its principles to technical purposes. It might be thought that the inclusion of a survey of chemistry within the compass of such a volume would necessitate an arbitrary choice of matter which must be limited as well as fragmentary and disconnected. Such is by no means the case. There is a wealth of matter, treated in adequate detail, and a flowing sequence recalling to memory some of the most entertaining of scientific lectures. Is it Professor Findlay's method of selection that has invested the book with a spirit of romance, or is it his peculiar gift for clothing his narrative with absorbing interest? How many people, for example, know that nitrogen was discovered and first prepared by a botanist, or that Robert Boyle was led to the discovery of what is now known as Boyle's Law by his interest in the machine then lately invented and called a "pneumatic engine," now more familiar to us by the name of "air pump"? On another page opened at random is found an illuminating account of the construction of different kinds of steel, with a beautiful description and a fine photomicrograph of Damascus steel: a description which contains a justification of the account given in Scott's *Talisman* of Saladin's exploit with a wonderful Damascus blade. The quotation is itself recited in a foot-note, and the reference chapter named. Next comes an account of the preparation of ink: what the colouring matter consists of and how it is dispersed in a colloidal form.

Writers may wonder how all this matter was introduced without conglomerate packing or the production of a bulging volume, and readers may wonder at their good fortune in finding just what they want most in so small a book. From among the ever-growing profusion of printed matter calling for notice an increasing proportion must be passed over for want of time to look at it. Any author, therefore, who selects and presents his matter in a form that will save the reader's time without prejudice to the subject is doubly deserving of gratitude. That is from the reader's point of view the author's most notable achievement, yet, it would be safe to guess, the idea was never present in Professor Findlay's mind. Rather he wrote as only one could write who was imbued with the spirit of chemistry.

[1] *The Spirit of Chemistry*. By Alexander Findlay, M.A., D.Sc. London and New York: Longmans, Green and Co. 1930. (Pp. xiv + 480; 88 figures. 10s. 6d. net.)

PATHOLOGICAL NEURO-HISTOLOGY

In his book on the histological technique of neuropathology[2] Dr. IVAN BERTRAND has given us not only the methods in general use in his laboratory at the Salpêtrière Hospital, but a complete compendium of modern methods of neuro-histology as applied to human pathology. Of special interest are his methods for photomicrography by the use of infra-red light to reveal the finer structure of nerve cells. But these form a technique of more than usual difficulty, necessitating the preparation of special sensitized plates. A full account is given of the gold and silver impregnation methods for neurofibrils and neuroglial tissues, which are being so continually modified and amplified that each new work on histological technique renders the last out of date in this particular. A useful section is also devoted to the degeneration products of myelin, and to special methods for glycogen, calcium, iron, and pigments. But in spite of its 376 pages the work is by no means complete, as many valuable methods and modifications have had to be omitted for lack of space. The book is valuable, not only for the new material which it includes, but also in that it gives details of the methods used in the chief neurological laboratory in France.

NOTES ON BOOKS

Dr. FRIEDRICH MAUZ has written a very serviceable little book[6] in which he outlines succinctly our present-day knowledge of the schizophrenic and manic-depressive psychoses. The symptomatology of schizophrenia is described and its prognostic significance inquired into, and a short chapter is devoted to the discussion of the nature of the underlying defect in this psychosis. The second part of the book consists of an account of the varied manifestations of manic-depressive insanity, viewed mainly from the prognostic angle. The views of Kraepelin and Kretschmer are deftly harmonized, and a short but significant introduction by the latter adds interest to the work.

In his book on Therapeutic Novelties[7] Dr. GASTON LYON reviews various aspects of modern therapeutics, and gives a short account of such subjects as serum therapy, endocrine therapy, psychotherapy, action of radiations, etc. He considers also other more general problems, such as the dosage of drugs, and the influence of age and sex upon the response to therapeutic measures. He has written some particularly interesting chapters on the subject of the general purposes of therapy, in which he follows out the argument that it is a patient, and not a disease, that receives treatment. The point is emphasized that an accurate diagnosis is the only sure basis of therapy, and that this includes not only the determination of the main disease, but also an assessment of the gravity of any added complications. Such complications can often be relieved, even though the main cause of illness cannot be attacked, and the patient is thereby rendered more able to resist the progress of disease. In general, Dr. Lyon advocates a rational form of symptomatic treatment. He expresses many interesting ideas that are the result of a long experience of medicine.

Professor ALESSANDRO PERI'S monograph on Industrial Medicine as an Italian Branch of Learning,[8] which won a prize offered by the *Rivista di Terapia Moderna e di Medicina Pratica*, is divided into two parts. The first, mainly historical, deals with the pioneer work on industrial medicine of Bernardini Ramazzini at the beginning of the eighteenth century, the psychological studies of workmen by Paolo Mantegazza, the studies of fatigue by Angelo Mosso, Maragliano's address on medicine in relation to social questions, the first university course on industrial diseases held by Luigi Devoto at Pavia in 1901, and the contributions to the subject of industrial medicine by other Italians, such as De Giovanni, Rummo, Ferranini, and Pende. In the second part Peri deals with the instruction given at the Italian faculties of industrial medicine, the articles pertaining to the subject in periodical Italian medical literature, and Italian participation in the various international congresses of industrial medicine. He concludes with the claim that industrial medicine is essentially an Italian discipline.

Dr. MOHR, in his book on the application of psychotherapeutic methods of treatment in organic affections,[9] discusses the reciprocal effects of mind on body. The psychological side of physical methods of treatment is explored, the combination of psychological with physical therapy discussed, and finally the various psychotherapeutic methods outlined—hypnotic suggestion, psychoanalysis, suggestion in the waking state, and re-education of the will. The latter part of the book comprises an account of the application of this form of therapy in such diverse conditions as cholecystitis, pulmonary tuberculosis, pneumonia, and epilepsy. There is a brief bibliography.

PREPARATIONS AND APPLIANCES

INSTRUMENTS FOR EXAMINING AND TREATING THE TONSILS

Mr. C. OSMOND BODMAN, F.R.C.S.Ed. (Clifton), writes: The instruments here illustrated have been found of great use in the investigation and after-treatment of tonsil cases.

The tonsil exploring hook (Fig. 1) is of a convenient size and shape for lifting the anterior faucial pillar off the tonsil,

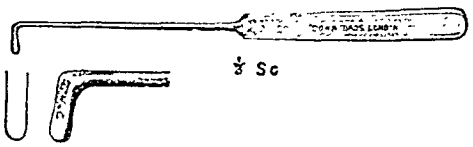

FIG. 1.

for raising the tonsil from the posterior pillar, for pressing upon the tonsil to squeeze out secretion, and for investigating crypts. The instrument is made in stainless steel, and, being somewhat hollowed and rounded, admirably serves the above-mentioned purposes without causing any injury.

The irrigating tongue depressor (Fig. 2), when connected with a Higginson syringe or irrigating can, serves the purpose

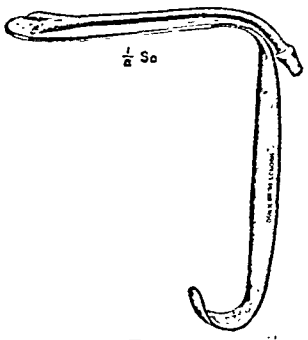

FIG. 2.

of douching the fossae with an antiseptic solution after dissection of the tonsils; it has proved popular with the hospital nursing staff. To use it, the patient sits forward over a basin so that the lotion runs freely in and out of the mouth.

These instruments have been made for me by Messrs. Down Bros., Ltd.

ARTIFICIAL PNEUMOTHORAX STOPCOCK AND NEEDLES

Dr. P. W. EDWARDS (Market Drayton) writes: The following is a brief description of a stopcock and needles used by me in my last 700 cases of artificial pneumothorax. The special feature is the simplicity and adaptability. There is a special stopcock, one end of which fits a Record needle and the other a Record syringe. This means: (1) that in an infant a hypodermic needle may be attached to the stopcock for the induction; (2) that, with my ordinary refill needle, on removing the stopcock irrigation may be undertaken through the refill needle; (3) that antiseptic solutions can be admitted through this needle by a Record syringe; and (4) that gomenol oil can likewise be introduced through this needle and a Record syringe.

There are three needles: (1) Induction needle. Length 4.5 cm.; needle fitting into a shoulder, the inside joint with the needle being a perfect cone, so that the stylet will pass without hindrance through the stopcock, the shoulder, and so to the needle point. The point of the needle is short, as on dental needles. Diameter of needle 0.035 inch, or 20 B.W.G.; stylet fitting through stopcock and needle with protruding 8 mm. (2) Refill needle. Similar to (1), but diameter 0.049 inch, or 18 B.W.G., taking correspondingly coarser stylet. This needle has a side opening, 5 mm. long by 0.5 mm. wide. (3) Refill needle. Same as (2), but has no side opening. The induction needle is fine enough for use without a local anaesthetic.

One stopcock only is needed. The needles can be supplied in any quantity. New needle shafts are cheaply refitted to the bosses; needles are resharpened at a low cost, and the stylets are very cheap, and protrude sufficiently to enable them to be heated and then withdrawn into the needles to dry them. Needles are thus not "flamed" and damaged.

The whole outfit, or parts, may be obtained from Messrs. Philip Harris and Co. (1913), Ltd., Edmund Street, Birmingham.

MEDICAL SELECTION FOR LIFE ASSURANCE

Broadly speaking, the tables of premiums used by a life assurance company represent the rates required to cover the risk in the case of an "average life." This implies a proposer in whom there are no factors in the family history, personal history, physical condition, habits, occupation, or milieu, likely to impair the normal expectation of life. Should any such impairment be present, the risk becomes an "under average" one, and the proposer is called upon to pay some extra premium or its equivalent in the form of a lien on the policy. The principle is clear, but the difficulty arises in deciding what constitutes an impairment, and, still more, in assessing it quantitatively. From the theoretical point of view it would be necessary to have a mortality table for each type of impairment, based upon a large number of cases, each exhibiting this particular impairment, and being in all other respects a normal risk. To construct such a table a large number of individuals would have to be included in each class, as a table based on a small number would inevitably tend to fallacy. This fact makes it difficult, though not impossible, to compile mortality tables for certain types of impairment, such as family history of diabetes, cancer, apoplexy, etc., and also for certain hazardous occupations.

In the case of impairments due to personal blemish, the difficulties are so great as to render accurate tables almost impossible. Consider, for example, a table for persons suffering from aortic regurgitation. One would require many thousands of cases, all suffering from this condition, with no other adverse feature. But they vary so much in severity as a result of differences in the extent of the valvular and muscular involvement, and the underlying etiological factor, that they would be a long way from the homogeneous group required. When to this difficulty is added the important one that the examinations are conducted by a large number of medical practitioners differing widely in diagnostic skill, it will be realized that the data constitute a heterogeneous mass incapable of giving trustworthy results. It is extremely doubtful whether any of the elaborate tables of personal impairments, even those of the American Medico-Actuarial Investigation of 1914, have more than a qualitative value, confirming the view that certain physical defects are a handicap to longevity, but failing to give an accurate measure of its extent. In America a system is widely used of assessing risks by an arithmetical method—taking the standard risk as 100, deducting marks for specially favourable features, and adding them for adverse ones. For the reasons given above, the system has not found much favour in this country, where the method is more frankly empirical, and consists, in essence, of collaboration between the actuary and the medical officer on the basis of experience and intuition.

The empiricism of our methods of assessment is strikingly reflected in a paper on "The selection of lives," read to the Faculty of Actuaries by Mr. Lewis P. Orr on December 1st, 1930. This was really a revised edition of an earlier paper on the same subject presented to the Faculty in 1919. Though written by an actuary for actuaries, it contains only a single mortality table (quoted from an American source); indeed, the whole paper is full of interest even to the least mathematically minded medical man, and can be read by him with complete understanding and enjoyment. It discusses, briefly but pointedly, all the principal impairments found in life assurance work, in family history, personal history and condition, and habits. In the first of these it is of special interest to find that Mr. Orr attaches little, if any, importance to a family history of cancer. He says: ". . . It was evidence such as the foregoing that led me in 1919 to express the belief that, while holding an open mind on the subject, it was probable that if future research should find that hereditary influence does bear a part, that part would be small. . . . During the intervening years, such evidence and statistics as came under notice tended to strengthen rather than weaken the opinion against hereditary influence." With regard to personal defects, the attitude towards some of them has been somewhat modified during the decade which has elapsed since the first paper was read. One of the most definite advances has been in the consideration of cases of glycosuria. An increasing use has been made of blood-sugar curves in the differentiation of true diabetes from other forms of glycosuria, with the result that cases of "renal glycosuria" are now often accepted as ordinary risks, especially for endowment policies maturing at a comparatively early age. As regards insulin, Mr. Orr mentions its beneficial effect in modifying the grave prognosis in ordinary diabetes, but he does not indicate how far its discovery is likely to affect insurance practice with regard to this disease. One of the difficulties is that there can be no guarantee that the proposer, if accepted, will continue with the dietetic restrictions and the injections necessary to keep the disease in check. The policy, once issued, is irrevocable; the holder's tenacity in maintaining the regime may be less enduring, with unfortunate results to himself and to the company.

Another condition which has attracted gradually increasing notice is that of hyperpiesia. In this field there has been a good deal of statistical work, principally in America, but also in this country by the Prudential Assurance Company, whose medical officer read a paper on this subject at the Bath meeting of the British Medical Association in 1925. All the published

results confirm the general impression that increasing pressure above the usually accepted normal connotes an increasing risk, and that a group of people with pressures over, say, 170 mm. Hg will show a definitely higher mortality than the average. There is no doubt that careful medical selection could do something in separating the more dangerous high-pressure cases from those in which the prognosis is relatively good. The presence or absence of signs or symptoms of impaired cardiac or renal efficiency, the family history, habits, and general physique of the proposer may all help, but even if all these points seem favourable, can one exclude the risk of a fatal apoplexy? Every practitioner can, of course, bring forward cases that he has watched for many years, little, if any, the worse for a pressure of 200 mm. Hg or more, but these individual exceptions do not invalidate the higher group mortality. As Mr. Orr points out: "If a practitioner should see 1,000 patients with high blood pressure at age 60 and bet with himself that 974 would survive the year" (the normal mortality), "and only 960 did survive, he would not feel downcast. In fact, he would probably point to the record with pride and boast of his ability in prognosis. But life insurance would have to tell him that his mortality was 150 per cent. in that group, and a medical director who never made a better guess than that would not keep his position for long. General medicine would look complacently at the living, but life insurance would ruefully regard the dead, for 40 claims would have to be paid instead of the 26 expected." Until medicine provides a more exact answer to the question of prognosis in such conditions, the companies are bound to protect their other policy holders by treating proposers manifesting these conditions as impaired lives, assessable, if at all, only on special terms.

TRAFFIC IN DANGEROUS DRUGS

It cannot be said that the report of the London conference on the limitation of manufacture of dangerous drugs, which has now been released for publication, marks any great advance towards achievement of the end in view. Last September the Assembly of the League of Nations, appalled by the disclosures of the huge illicit traffic in dangerous drugs, unanimously desired that steps should be taken, without delay, to limit the production of the drugs in question to the amounts required for medical and scientific purposes. The League's Advisory Committee on Opium was to prepare plans for that purpose, and the Council was to summon a conference, in May next, at which both manufacturing and consuming countries would be represented, to consider the draft plans in order to implement the International Opium Conventions of 1912 and 1925. At the instance of the Advisory Committee a "preliminary conference" was convened in London last October, at which it was hoped that the producing countries, or the drug manufacturers therein, might agree on the quotas of morphine, heroin, and cocaine to be allocated to each country out of a total to be fixed for legitimate world consumption. In addition to France, Germany, India, Italy, Japan, the Netherlands, and Switzerland, which accepted the invitation of the British Government to send representatives to the conference, the United States, which is not a party to the Geneva Convention, sent a delegate, while Turkey and Soviet Russia, which are parties to no convention, were, for the first time, represented.

On the main question the report states: "The Conference regrets that it has not been able, in the course of its session, to come to a definite conclusion as to the allocation of the quotas among the manufacturing countries." The manufacturers of the five largest exporting countries, though in negotiation since the summer, had not completed their labours when the conference met. Some provisional figures which they put in were criticized on various grounds, notably by the delegates of Great Britain and India, and "in these circumstances the Conference felt that the whole question required further investigation," although in the case of cocaine some quotas appear to have been provisionally accepted. Whether the manufacturing firms should be the sole, or the chief, arbiters in determining the national quotas is, to say the least, doubtful. It appears that the figures they vouchsafed had more regard to the sales by individual firms than to legitimate national productions. Insufficient allowance seems to have been made for the amounts that had gone into illicit traffic, and, indeed, no very obvious relation could be established between the manufacturers' quotas and the official statistics prepared by the Secretariat of the League of Nations. The enormous quantities of morphine and heroin exported from three recently established manufactories in Turkey had not been reported to the League's Central Opium Board by any of the countries to which these huge illicit exports were stated to have been consigned. Meanwhile, the Turkish delegation was prepared to participate in international control of the drug traffic, provided that its quota should be equal to one-third of the world production!

Another point which engaged the attention of the conference was in regard to the large quantities of morphine made, not for use as such, but for conversion into other substances, notably codeine. This latter alkaloid, though at first included under the draft Hague Convention, at the instance of the British delegation, was finally omitted at the desire of the German representatives. Consequently, morphine which has been converted into codeine is not deemed to be subject to control. Other questions arose which were held to be outside the scope of the conference, inasmuch as they concerned the consuming as well as the producing countries, and the Soviet delegation maintained, with some plausibility, that the limitation of production should apply, not only to alkaloids derived from opium and from the coca leaf, but also to these raw materials themselves.

SOURCE OF INFECTION IN PUERPERAL FEVER

A report has just been issued by the Department of Health for Scotland dealing with researches by Dr. John Smith of the City Hospital Laboratory, Aberdeen, into the causation of a group of cases of puerperal fever and septic abortion occurring in Aberdeen over a period of eight years.[1] It supplements the investigation of maternal mortality in Aberdeen for the decennium 1918–27, which was undertaken by Dr. Smith, in association with Drs. Parlane Kinloch and J. A. Stephen, and to which many references were made in these columns two years ago. The report deals specially with the source of infection in 18 cases of puerperal fever and 3 cases of septic abortion, based on bacteriological examination of the secretions and excretions obtained from the patients, and of materials, chiefly throat and nose swabs, obtained from doctors, nurses, and others in attendance on these patients. During these eight years all cases of puerperal fever admitted to Aberdeen City Hospital for Infectious Diseases have been subjected to routine bacteriological investigation, with special reference to the presence of the *Streptococcus haemolyticus*. In the present report an analysis is given of the bacteriological findings in 221 cases of puerperal fever and 25 cases of septic abortion. The *Str. haemolyticus* has been found to be associated with fatal cases in a manner which leaves no doubt as to its relative importance in puerperal fever. It was found in uterine cultures from 149 of the cases, and in 120 of these cases occurred alone. It was also recovered from blood cultures in 22.9 per cent. of the cases, while other organisms were found in 3 per cent. Out of 46 cases that proved fatal, this organism was obtained from one or more sources in 43 instances. In 25 cases of septic abortion studied, this organism was obtained in pure culture from the uterus in 11 cases, and in 3 others *Bacillus coli* was found. In the cases which were specially studied in regard to the bacteriology of the secretions, both of patients and of contacts, the cultural and serological characteristics of the various strains of *Str. haemolyticus* and *B. coli* that were obtained were fully investigated. In 15 cases the only organism isolated from the uterus was the *Str. haemolyticus*, and the source of infection was discovered in 12 of these. In 3 cases *B. coli* only was obtained from the uterine cultures, and its source was discovered in each case. In 12 cases the infecting strain of the streptococcus was found to have had its origin in the throat or nose of the doctor, nurse, or student in attendance; in only one case was the infection of autogenous origin—from a septic focus on the patient's hand. In infections due to *B. coli* it was found that the organisms were derived from either the urinary tract or the intestine. It is suggested with regard to prophylaxis that infection might be prevented if doctors, midwives, and maternity nurses were to make a wider use of masks and adopt more careful antiseptic treatment for the hands. Dr. Smith suggests further that, in hospitals, definite bed isolation by means of metal and glass screens interposed between the patients should be introduced. "As soon as it is generally recognized by practising physicians and maternity nurses that in the majority of cases of puerperal fever the infecting organism is introduced from an intrinsic source, and as soon as a satisfactory surgical technique is evolved for conducting a confinement, then there is bound to follow a large decline in the number of cases of this disease."

AFTER-HISTORY OF TUBERCULOUS PATIENTS

Each year the London County Council publishes particulars of the after-history of patients who were receiving residential treatment under its tuberculosis scheme five years earlier. The cases are arranged in categories: A, sputum-negative cases; B, sputum-positive, the latter being divided into three groups. The category B1 comprises cases with slight constitutional disturbance, if any, and with obvious signs of very limited extent; B3, cases with profound systemic disturbance or constitutional deterioration, and all cases with grave complications; and B2, all cases not falling into Groups 1 and 3. Class A and B1 may be considered early cases; B2, moderately advanced; and B3, far advanced. In 1924 4,314 adult patients were discharged from treatment. In 227 cases the diagnosis of tuberculosis was not confirmed; 54 were discharged from observation hospitals and not transferred to sanatoriums; and of the remainder, 402 are not now traceable. The number of cases investigated after the completion of five years is therefore 3,631. The following is the result, P. standing for pulmonary and N.P.S. for non-pulmonary surgical.

Class		Total Cases	Alive after 5 Years	At Work, or Fit though Unemployed
Males:				
A and B1	P.	428	330	230
B2	P.	1,285	442	209
B3	P.	197	27	8
N.P.S.		137	101	75
Females:				
A and B1	P.	257	121	141
B2	P.	585	161	101
B3	P.	221	9	2
N.P.S.		137	83	65

During 1924, also, 775 children were discharged from residential institutions after having received at least one period of residential treatment. After deducting patients in whom the diagnosis of tuberculosis was not confirmed, those in respect of whom reports are not available, and those who have died from some other disease, an examination of the after-histories of the remaining 559 children shows that 114 out of 175 pulmonary patients, and 341 out of 384 non-pulmonary patients, are still alive.

THE NATURE OF THE VITREOUS

The fourth monograph supplement of the *British Journal of Ophthalmology*, issued in December, 1930, bears the above title, and is the work of Mr. Stewart Duke-Elder.[1] It incorporates work done for the Medical Research Council, and amplifies the author's previous monograph on the nature of the intraocular fluids, which was noticed in our columns on May 1st.

[1] The Nature of the Vitreous Body. By W. Stewart Duke-Elder. *Brit. Journ. of Ophthalmol.*, Monograph Supplement 4. London: George Pulman and Sons, Ltd. 1930. (5s.)

1927. The work is largely biochemical, and it will probably suffice to quote one of the opening paragraphs in order to give our readers some idea of the contents. The author brings forward evidence to show that "the vitreous body is a hydrophilic elastic gel; that it is formed upon the basis of special protein constituents elaborated by the surrounding ectoderm, and that the common intraocular fluid (which is a dialysate of the capillary blood) percolates these, combining with them to form a gel; that the reactions of the vitreous body to changes in its environment and in its internal economy proceed along physico-chemical lines according to the conditions which govern the behaviour of gels in general." The last seven pages of the monograph discuss shortly various clinical problems on which the nature of the vitreous has a very definite bearing, such as the relation of the turgescence of the vitreous body to glaucoma; the breakdown of the vitreous gel and the nature of vitreous opacities; and retinal detachment. A very full bibliography adds materially to the value of the work, which, in our opinion, enhances the reputation already possessed by the author for extensive and accurate research work. Undoubtedly it is a very difficult subject.

A CHINESE MINING HOSPITAL

The Kailan Mining Company is a fusion of British and Chinese mining interests, brought into being by the successful working of the huge coal area in North China which was developed by the Chinese Engineering and Mining Company, a British concern. For the past thirty years the company's hospital has been recognized in China as a model institution, well able to look after the medical and surgical needs of over 30,000 local employees. The medical work of the administration (under the direction of Dr. J. B. G. Muir, who has compiled a report for the year ending June 30th, 1930) has now been reorganized into four district hospitals, auxiliary to a general base hospital at Tangshan, the principal medical officer being its consulting surgeon. The extent of the work is shown by the fact that there were 4,301 in-patients during the past year, with an average mortality of 3.27 per cent., and 233,185 out-patient attendances. Despite the healthy climate of North China the problem of maintaining efficient sanitation in large industrial communities is greatly hampered by the ignorance of the individual in matters of personal and public hygiene, and the official apathy as regards gross defects in matters of public sanitation. On the whole the past year has been very satisfactory from the general health standpoint. During the first three months of 1930 numerous cases of influenza of the respiratory type occurred, and a very high incidence of venereal infection is also noted. The men are reluctant to complete a full course of antisyphilitic treatment, the average patient being contented as soon as his immediate symptoms are relieved. Though there is as yet no Workmen's Compensation Act in China, the present report is interesting as showing how the miners have become alive to the opportunities which the certification of injuries offers. An increased use of safety appliances in the mines was followed by a reduction in the number of serious injury cases, and a decrease of 16 per cent. in fatal injuries. But while the actual number of minor injuries sustained has not increased, the number of employees reporting themselves for treatment and certification of minor injury has doubled per unit of output. Thus in 1928–29, for each 10,000 tons unit of coal obtained, there were thirteen accidents, and in 1929–30 there were twenty-six. This increase is attributed to the mining company's decision in July, 1929, to grant certificates in respect of injuries causing incapacity for a minimum of three days, whereas formerly certificates for sick pay had not been given for less than five days. The labour unions have encouraged their members to apply for sick pay in respect of injuries so slight that formerly the employee would not have presented himself for treatment. This is an experience that applies to most modern industrial concerns in China.

"ERYTHROCYANOSIS CRURUM"

The detrimental effect of cold on the skin, in the guise of frostbite and chilblains, has long been a commonplace both to the medical profession and to the lay public. But in recent years further attention has been directed to this subject, first by the so-called trench foot, of which many thousand cases occurred during the war, and since then by an almost new affection of the skin which is the direct consequence of feminine fashion. This novel complaint is dignified by the name "erythrocyanosis crurum puellaris," a name which is self-explanatory, for, translated into the vernacular, it signifies that its victims are young women, and that they suffer from a bluish-red discoloration of their legs. This condition, first noticed by Balzer and Alquier in 1900, but only observed frequently during the last twelve years, is undoubtedly due to the fact that skirts have been shortened, and that the use of silk stockings has become almost universal among the present generation. Hence the common occurrence of this peculiar derangement of the cutaneous circulation in the legs of the modern young woman, which, owing to its etiology, has been dubbed by the irreverent "silk stocking disease." In Haxthausen's recently published volume entitled *Cold in Relation to Skin Diseases*[1] the condition is fully discussed, and the author finds himself in agreement with Klingmüller and Dietrich in ascribing it entirely to the effect of prolonged exposure to a moderate degree of cold, and in discarding the notion that it must be associated with the constitutional abnormalities invoked by other authors, such as disturbances of the endocrine glands. He points out that the vascular changes are identical with those which affect the legs of normal women on exposure to a lesser degree of moderate cold, and that no sharp differentiation is possible between these and cases of fully developed erythrocyanosis crurum. There is really no relationship between this condition and the much more serious erythema induratum, usually known as Bazin's disease, although the more severely congested areas in erythrocyanosis do undoubtedly bear a considerable resemblance to the lesions of erythema induratum before ulceration takes place. But Bazin's disease is a tuberculide, while erythrocyanosis carries with it no tuberculous stigma. Acrocyanosis or erythrocyanosis is much more closely related to the familiar chilblain, with which, indeed, it

[1] *Cold in Relation to Skin Diseases.* By H. Haxthausen, M.D. Translated from the Danish by Jenkins Oliver, M.D. Copenhagen: Levin and Monksgaard; London: W. Heinemann (Medical Books) Ltd. 1930. (Pp. 163. Paper cover, 13s. 6d.; cloth, 15s.)

is not infrequently associated. The main difference between it and ordinary perniosis is that inflammatory changes are inconspicuous or absent in the large areas which spread diffusely over the legs of the victims. As in the common circumscribed forms of perniosis the coagulation time of the blood is prolonged, and it is said that the arterial blood pressure is lowered, while the pressure in the subcutaneous veins is raised, and Layani states that the heart in most cases is perceptibly smaller than normal. Effective prevention and treatment would obviously consist in more adequate protection of the legs against cold, but most young women would rather follow the prevailing fashion than wear woollen stockings and long outdoor skirts in order to escape a complaint which only causes them a moderate amount of discomfort. *Il faut souffrir pour être belle.*

BRITISH CHEMICALS AND DRUGS

Arrangements for the 1931 British Industries Fair, to be held at Olympia during the last fortnight of February, are now nearly complete. Medical visitors should on no account miss the section dealing with chemicals and drugs, druggists' sundries, and scientific apparatus (including medical and surgical instruments and appliances), all of which will be found near together in the main hall. The resources of British industry in the realm of medicinal products are not as widely recognized as they should be. It is true that before 1914 this country depended largely on the Continent for many of the most important fine chemicals required by medical science, and there was a natural tendency to ascribe special merits—which in fact they often possessed—to the products of the German chemical and drug industries. It was only when cut off from this source of supply by the outbreak of war that our countrymen realized the importance of a well-organized and enterprising British industry which could supply the wide range of medicinal products required for a scattered Empire. British manufacturers responded successfully to the emergency, and with the post-war stimulus given by the Safeguarding of Industries Act, 1921 (Key Industry Section), it has since developed in a remarkable manner, until it can now bear comparison with any of its competitors. There are obtainable to-day in this country, at competitive prices and of the highest quality, medicinal substances of all kinds, such as anaesthetics, antiseptics, soporific drugs, synthetic remedies, and biochemical products. Since medical men sometimes find difficulty in ascertaining the British manufacturers of a particular product, attention may be drawn to the *Directory of Fine Chemicals*, recently published by the Association of British Chemical Manufacturers, which contains an alphabetical list (with the names of makers) of over 3,000 chemicals, a large proportion of which are of importance in medical practice or research. This can be obtained gratis from the office at 166, Piccadilly, W.1, and we are informed that the association is prepared to advise as to the makers of products which are not in the *Directory*, to make special arrangements for their manufacture, or to deal with any difficulty that may arise regarding the British products. It desires full collaboration with the medical profession in such matters, and has for some time been working in close touch with the Chemotherapy Committee of the Medical Research Council, and with the Colonial Research Committee in the production of new substances required for extended clinical trials. It is hoped that medical practitioners will make free use of this offer and do all they can to support British industry at a time when such encouragement is greatly needed.

INTERNATIONAL CONGRESS OF HISTORY OF SCIENCE

The second International Congress of the History of Science and Technology will be held at the Science Museum, South Kensington, from June 29th to July 3rd, under the presidency of Dr. Charles Singer. The congress originated with the Comité International d'Histoire des Sciences, which was founded at Oslo on August 17th, 1928. This body meets annually in Paris, and organizes every three years a congress in which persons interested in the history of science and technology are invited to take part. For the coming congress it has been fortunate in enlisting the co-operation of its parent body, the Comité International des Sciences Historiques, together with that of two other international societies, the History of Science Society, New York, and the Newcomen Society for the Study of the History of Engineering and Technology, London. The aim of the congress is to provide opportunity for intercourse and exchange of thought between all those who are interested in the various departments of the history of science and technology. The programme will include, in addition to the reading of scientific communications at the morning sessions, social gatherings, visits to Kew Gardens, Down House, Greenwich, Barber Surgeons' Hall, the Royal College of Physicians, the British Museum, the Natural History Museum, and the National Portrait Gallery, and excursions to Oxford and Cambridge. Further particulars can be obtained from the honorary secretary, Mr. H. W. Dickinson, Science Museum, South Kensington, S.W.7.

The Morison Lectures before the Royal College of Physicians of Edinburgh will be delivered in the hall of the College, 9, Queen Street, Edinburgh, by Dr. D. K. Henderson, on February 9th, 11th, and 13th, at 5 p.m. The subject this year is social psychiatry.

We have to announce with much regret the death, on January 26th, of Dr. Archibald Leitch, director of the Research Institute of the Cancer Hospital, London, and professor of experimental pathology in the University of London.

We regret to announce the death of Dr. John Edward Gemmell, honorary consulting surgeon to the Liverpool Maternity Hospital.

The next reception of the Royal Society of Medicine will be held on Wednesday, February 18th, at 8.30 p.m., when Fellows and their friends will be received by the President and Mrs. Watts Eden. At 9.15 p.m. Dr. H. Letheby Tidy will give an address on "Poisoners of ancient times." Admission by ticket only, applications for which should be addressed to the secretary, 1, Wimpole Street, W.1.

PRESENTATION TO SIR D'ARCY POWER

CEREMONY AT ST. BARTHOLOMEW'S

As briefly stated in our last issue, on Wednesday, January 21st, at St. Bartholomew's Hospital, Lord Moynihan, P.R.C.S., handed to Sir D'Arcy Power, on behalf of the subscribers, the volume of Sir D'Arcy's *Selected Writings* which has been prepared in commemoration of his seventy-fifth birthday. A large gathering of subscribers and friends assembled in the Great Hall, under the chairmanship of Lord Stanmore, treasurer of the hospital.

Lord MOYNIHAN, in making the presentation, said: A multitude of diverse duties fall to the lot of the President of the Royal College of Surgeons, but I can truthfully say that no more pleasurable obligation has been laid upon me during my term of office than that which I am asked to fulfil to-day. I am frequently, and perhaps a little imperiously, reminded by my numerous St. Bartholomew's colleagues on the Council of the College that whereas they enjoy the dignity of membership of your staff, I am to be regarded only as one of your students. But even that minor office carries to my ears a title of great honour. The members of the staff of this oldest and most renowned of British hospitals have not always been men of the highest professional distinction, though both you and they might be greatly surprised to hear so gruff a statement made in regard to them; but more often than in the case of any other hospital, they have been men of distinguished character and fine general culture—great even in truancy—who have added to the renown and respect of our profession. I like to think that of three supremely great Englishmen in medicine, Harvey was a physician to this hospital; Hunter, our patron saint at the College, was a student under that great little gentleman, Percivall Pott; and it is difficult to believe that Lister would have escaped you had he not been a Quaker. I am therefore full of pride at your request to return to what I will venture to call, I hope without arrogance, my old hospital. The occasion of my return makes a very warm appeal to me; for I am asked to help you in doing honour to an old and beloved colleague. It is, I think, significant and delightful that the initial impulse and the sustaining power of this project came from the younger men, and is associated with the energies of the Osler Club, and I may perhaps be permitted to mention the names of W. R. Bett and A. W. Franklin.

Sir D'Arcy Power, the most eminent medical historian of our day, illustrious son of a distinguished father, is, it is perhaps unnecessary in view of his distinguished career to say, a Yorkshireman. He joined the Council of the Royal College of Surgeons on the same day as myself. He has held many offices, and one, that of honorary librarian, has, in view of his high accomplishments, deep and accurate knowledge, and unwearied service for us, been created for him. The fact that he has served his full period upon your staff is in itself the testimony he would himself most value as to his surgical distinction. Yet when the name of D'Arcy Power comes to my mind, or his familiar image to my eye, I recall on the instant, not his career as a surgeon, not even his unrivalled knowledge of surgical history, from which the *British Journal of Surgery* has continuously and greatly benefited, but his friendliness, his cheery disposition, and his beauty of character. When we call to mind the names and services of our professional friends, we judge them, I think, not by the size of their practice, nor the money they have with so great difficulty accumulated, nor by their contributions to the science, the craft, or the lore of medicine, but by their character and their influence upon the younger members of our calling, through whom they earn immortality. For it is not by his wealth, nor by his learning, nor even by his wisdom that a man is rightly esteemed, but by his character. Judged by this sternest of all standards, you will all at once agree, D'Arcy Power has been one of the greatest influences in medicine in our day. He has been prudent in counsel, wise in action, eloquent in word written or spoken, imperturbable and resolute in time of challenge and difficulty, a staunch, loyal, happy friend whom all men have welcomed and trusted and loved.

Lord Moynihan then handed the book to the recipient.

Sir D'ARCY POWER, who was received with long-continued applause, said: My instructions are that I should be brief, very brief indeed, but my feelings are so deep that I can hardly express them at all. I am afraid that Lord Moynihan has spoken with the tongue of partiality and biased friendship. I have not deserved the half of what he has said. All that I can say for myself is that I have had a good memory, and when I have been asked a question I have tried to reply to it from such knowledge as I possess. Sometimes I have been fortunate, sometimes I have been wrong. I have been at many meetings in this hall, and seen many presentations, but this occasion to me is quite unique. On all previous occasions it has been the presentation of a portrait. I do not know of an occasion on which pupils—if I may use that expression—have given their master a selection from his own writings. I think that must stand absolutely by itself. When a book has been given—and that form of presentation has been adopted on the Continent and in the United States, and occasionally in this country—the contributions in the book have always been made by the pupils themselves. It was thought, I suppose, to be more appropriate that the master should not be reminded of the very poor things that he had often written himself. But this occasion is unique in that the volume presented to me consists of my own writings, and I have to thank, not only the Osler Club, who were the begetters of this beautiful idea, but also Mr. Franklin and those who have carried it into execution. As I look through the book I can see that it is beautifully produced, as a book-lover would love to have his writings preserved. The paper is good, the inscription goes to my heart, the pages are beautifully set out. *Simplex munditiis.* And I see that the production is in the very best style of the Clarendon Press. Then I notice how excellent is the binding, and there I am sure my sister (Mrs. Loosely), who is a first-rate binder, has evidently been at work and has put her whole heart into this undertaking and made it as pleasing as it can be. I feel sure that there is an undercurrent of feeling in all this which will certainly leave a lasting memory of personal affection, making this no stereotyped presentation in any way. It seems to me that in some way quite unknown to myself I have entered into your hearts, and I am quite sure, as we have been taught in other places, that it is better to live in the hearts of men than to rule over their lives and fortunes. I am in that fortunate position with respect to all those who have taken part in the presentation of this volume, whom I thank very heartily.

Professor G. E. GASK said that there had been a large number of letters from subscribers regretting their inability to attend, but he would read only three telegrams, one from the Institute of Medical History in Leipzig, sending heartiest greetings and best wishes to Sir D'Arcy Power; another from Professor Karl Sudhoff, also of Leipzig; and the third from Sir Robert Jones, all uniting in doing honour to their distinguished friend. Professor Gask went on to say that he would like to offer the thanks of those assembled to one of the more recent "perpetual students" of St. Bartholomew's—namely, Lord Moynihan—for coming there and giving one of his charming speeches, which had been listened to with so much pleasure. Lord Moynihan had spoken of Sir D'Arcy Power as a surgeon, a medical historian and bibliographer, and librarian of the Royal College of Surgeons, and nothing could be added to the way in which he had done so. But he himself had known Sir D'Arcy Power for more than thirty years, and he wished to add one small touch of personal reminiscence. He remembered him when he was appointed to the hospital as assistant surgeon, and from that time onwards one of his chief characteristics was his sunny disposition. That characteristic had remained with him through all his

long life, had helped him through some great sorrows, and left him with a smile on his face and a merry wit. The work in connexion with the volume which had been presented was a great pleasure to all who had been engaged in it. The idea was evolved by the Osler Club, who had borne the brunt of the work. It had been a labour of love. He called upon the gathering to express its thanks to those who had had the presentation in charge, also to Lord Stanmore for presiding, and to Lord Moynihan for making the presentation.

SIR D'ARCY POWER'S WORKS

We suspect the members of the committee entrusted with the preparation of the Birthday Volume* of having an eye to their own and the subscribers' interests as well as to the honour of their hero. Had they chosen to undertake a *festschrift* after the German fashion, we might all have possessed a number of essays by distinguished pupils of the Master, but we should still have lacked what has been long wanted, a collection of his writings. It is not complete. It would have been impracticable to include all the more fugitive publications, for Sir D'Arcy Power has been a prolific writer, and many a Nova et Vetera article in our columns has owed its attraction to his wit, humour, and scholarship. The history of British medicine and surgery is a subject which has been made peculiarly his own, as a cursory glance at the contents of this volume will show. Even those who have some knowledge of his industry, erudition, and wide interests will, we think, be surprised to find that the short-title bibliography attached to this collection contains 609 entries. Drs. A. H. T. Robb-Smith and Alfred Franklin tell us that Sir D'Arcy contributed 185 articles to the *Dictionary of National Biography*, and that "scarcely a number of the *British Journal of Surgery*, since the first in 1913, has lacked an 'eponym' an 'epoch-making book,'" or the biography of a bygone surgeon from his pen.

Of the sixteen articles in this commemorative volume all but two are on historical or biographical subjects, and it is only by reference to the bibliography that we realize how much valuable work Sir D'Arcy Power has accomplished in surgery and pathology; but, conditions of space apart, it is unfortunately true that scientific essays and records lose their interest with the swift advance of knowledge far more rapidly than historical work, which if true at the outset, remains so indefinitely. Faced by the disagreeable necessity of rejecting a great mass of articles, the editors were doubtless wise to choose the non-scientific in a proportion of seven to one. The two surgical articles on the palliative treatment of aneurysm and on cancer of the tongue fully justify their choice. The records here given of thoracic and even abdominal aneurysms wired with Colt's apparatus remind us strongly that this treatment affords a hope of relief from pain, and of prolongation of life, in what are otherwise hopeless cases. The Bradshaw Lecture on cancer of the tongue is a most valuable contribution to the subject. Sir D'Arcy points out that there is no record of this disease till 1635, and that its increase has marched in step with the increased use of tobacco for smoking. Time alone will show whether the prophecy of a great and sudden increase of cancer of the tongue in 1950 is fulfilled.

The fourteen historico-biographical articles which form the bulk of the book offer a rich feast. Very properly the Hunterian Oration on "John Hunter a Martyr to Science" takes the first place with its interesting illustrations from Jesse Foot. Sir D'Arcy has well brought out the personal attraction which was felt by all who had much to do with the "Dear Man." The Harveian Lecture, delivered before the Harveian Society in 1914, on "English Medicine and Surgery in the Fourteenth Century," and the second Vicary Lecture on "The Education of a Surgeon under Thomas Vicary," are full of information and curious lore. "John Ward and his Diary" gives an insight into the daily jottings of a medically minded parson in the seventeenth century, and discloses the nearly concealed fact that it is the outcome of four years' work of transcription of the sixteen small books of crabbed writing, which have since been sold by the Medical Society of London. Like a good and worthy follower of Rahere, Sir D'Arcy has written much on St. Bartholomew's Hospital, and the editors have included several essays on it and on William Harvey, who adorned the charity by his service. The humours of the examination hall of the College of Surgeons in the eighteenth century are enlivened by old caricatures, and many of the other chapters are well illustrated. This volume is printed and bound by the Oxford University Press. It is needless to say that it is well done.

THE TREATMENT OF CIRCULATORY FAILURE

At a meeting of the Royal Medico-Chirurgical Society of Glasgow, held on January 9th, Professor W. T. RITCHIE of Edinburgh delivered an address on "The treatment of circulatory failure," of which the following is an abstract.

Failure of the circulation is one of the problems which frequently confront every medical practitioner. In acute infective diseases and in many chronic diseases he is on the watch for a failing circulation, and strives to combat it. To the surgeon the problem presents itself as wound shock, death under general anaesthesia, and post-operative collapse of the lung.

Acute Circulatory Failure

When circulatory failure is acute the heart is not necessarily at fault. In syncope, wound shock, and experimental histamine shock, it is at the periphery that the circulation fails; the arterial pressure falls, the pulse becomes weak and rapid, the skin pale, cold, and moist. Further, intravenous injection of the nucleic acid derivative, adenosine, may be followed by pallor, giddiness, and faintness, which are doubtless attributable to sudden general arterial dilatation, because this is one of the pronounced actions of adenosine in the animal used for experiment.

The most frequent form of acute circulatory failure observed by the medical practitioner is toxaemic shock, which may develop in acute infective diseases, and especially in acute pneumonia. The patient may become collapsed, the arterial blood pressure falling. We are inclined to refer the collapse to "heart failure," and to consider the myocardium as being gravely weakened by bacterial toxins. We are clinging to a belief which may be as false as that which led the physician a hundred years ago to bleed his pneumonia patient freely. Acute cardiac failure in pneumonia is, I believe, often a direct sequel of failure at the periphery.

As to treatment, evidence may be adduced in favour of administering antipneumococcal serum, provided it can be given within the first two or three days of the illness, but our efforts are mainly directed to reducing the ill effects that follow in the train of the infection, of which anoxaemia is probably the most important. Oxygen should be administered as early, freely, and continuously as possible, preferably by means of a Haldane mask. To give oxygen through a funnel is a futile, wasteful procedure. The administration of 5 per cent. carbon dioxide with oxygen may also be recommended, not only because of its beneficial influence on the vasomotor centre, but because it increases the depth of respiration. The exhibition of digitalis in small doses in pneumonia does not appear to rest on any solid basis. In cases where acute circulatory failure has developed, the intravenous injection of 1/250 to 1/120 grain of strophanthin is sometimes attended by undoubted benefit. In the incipient phase of toxaemic shock the drug that is of most value is strychnine, 1/60 to 1/30 grain, given subcutaneously every four hours. Adrenaline, too, is sometimes beneficial, but the action is evanescent, and ephedrine is preferable. In the later stages of toxaemic shock, where the vasomotor

centre is perhaps exhausted, intramuscular injections of pituitrin are of value, by constricting the arterioles, and raising the arterial blood pressure. I am not yet convinced that any therapeutic benefit is to be gained from the administration of camphor, cardiazol, or other substances whose pharmacological action is primarily that of a local irritant. Alcohol should seldom be recommended.

Acute Cardiac Failure

Acute cardiac failure in its most grave form ensues when the coronary blood supply to a considerable proportion of the ventricular muscle is suddenly cut off by coronary thrombosis. Amyl nitrite is worse than useless, because the patient is collapsed and the blood pressure has fallen; morphine is the sole means of allaying the patient's anguish. Ammonia and alcohol are of temporary benefit in some cases; if the pulse is weak and rapid, trial may be made of strophanthin intravenously, but this is not unattended with danger, as it may precipitate a fatal issue by causing ventricular fibrillation.

Paroxysmal tachycardia of auricular origin may promptly be arrested by digital compression on the vagus nerve or the adjacent carotid sinus in the neck. The reflex initiated in the wall of the carotid sinus is transmitted to the heart by the vagus. In some patients the regular administration of quinidine may ward off attacks of auricular tachycardia.

The treatment of auricular fibrillation of toxic origin may vary from a mercurial purge and saline to radium or thyroidectomy, as required. In all cases, except those with an infrequent ventricular rate, digitalis is of great benefit. With acute rheumatic carditis the prognosis is usually favourable, provided the patient can enjoy complete rest for many months, and has no foci of infection.

Chronic Cardiac Failure

Cardiac dilatation is often ascribed to "loss of tone" of the heart muscle, but it is still doubtful whether the mammalian heart has the property of tone. The latest conception of chronic cardiac failure, based on the researches of A. V. Hill, Eppinger, V. Romberg, Jervell, and others, lays stress on the metabolic disturbances which accompany, aggravate, or may even induce this failure. The observations of Peabody, Meyer and Du Bois, Grafe, and Händel had indicated that the basal metabolic rate of compensated heart cases was within normal range, but that it was high if the patient was dyspnoeic. A high basal metabolic rate in cardio-vascular cases is one of the fundamental phenomena upon which Eppinger and his collaborators have built their interesting conception of cardiac failure. The conclusion we may draw is that the cardiac patient who is not breathless has a normal basal metabolic rate. With the evidence now available it seems probable that metabolic disorders in cardiac patients are a consequence rather than the cause of cardiac failure.

Treatment should include confinement to bed in the semi-recumbent posture. It is seldom advisable to restrict the fluid intake, but if the patient is dropsical a salt-free diet helps to promote diuresis. If a hypnotic is needed, chloramide, morphine, or heroin may be used. Digitalis, probably one of the drugs most commonly abused, is indicated when the heart's action is fast and failing, and when this failure is associated with auricular fibrillation. It is admittedly of less service when the heart is maintaining a normal rhythm; strophanthus is a reliable and safe substitute for digitalis. The dosage of digitalis should be determined by the patient's need and his response; massive doses should be reserved for urgent cases with an extremely high ventricular rate. In a case of grave urgency the intravenous injection of strophanthus is called for. The oral administration of ouabain is not satisfactory.

Once the patient is digitalized the daily amount of digitalis can be reduced until we have ascertained the maintenance dose which, by holding the ventricles in check, suffices for the best circulation available. For the purpose of restoring the normal cardiac rhythm the most potent drug is quinidine; it is contraindicated when there are signs of gross cardiac failure because, even if the normal rhythm is restored—which is unlikely—the cardiac failure will be less readily controlled than when the auricles were fibrillating. Quinine by oral and intravenous administration yields results less favourable than quinidine; adenosine fails to arrest auricular fibrillation and flutter in the human subject, because it causes faintness and other disquieting symptoms. Plasmoquine failed in the two cases in which I have tried it.

In every case of chronic cardiac failure it is important to ascertain the functional efficiency of the kidneys. If a salt-free diet and digitalis do not disperse the dropsy, other measures should be taken to promote the elimination of water. The administration of theobromine sodium salicylate, in ten-grain doses, three times daily, is usually followed by copious diuresis. The action of theocine is less certain, and of caffeine less efficacious, but when combined they are sometimes most effective. Urea acts well, and mercury combined with digitalis and squill is beneficial. Novasurol and salyrgan should be reserved for cases that have failed to respond to other remedies. The mercurial diuretics are contraindicated if the kidneys are grossly diseased. If diuretics fail, the introduction of a Southey tube into one of the lower limbs, or paracentesis of the pleural sac, is indicated.

Where chronic cardiac failure occurs in association with advanced arterio-sclerosis attempts to lower the arterial blood pressure are inadvisable. Thyroid extract is of service in mildly myxoedematous cases with hyperpiesis. Should the arterial pressure of the cardio-vascular patient rise decidedly higher than his usual level, rest in bed is indicated. One grain of emetine injected daily may lower the pressure, and venesection may be required.

Where the primary cause is rheumatic infection, foci of sepsis should be removed; where the origin is syphilitic no antisyphilitic remedies other than mercury or iodide should be given until a reasonably efficient cardiac action has been regained. In cases of fibrillation due to secondary toxic goitre, digitalis followed by quinidine should be given to restore the normal rhythm, and thyroidectomy performed to obviate the imminent risk of cardiac failure recurring, or the greater danger of a hyperthyroid crisis.

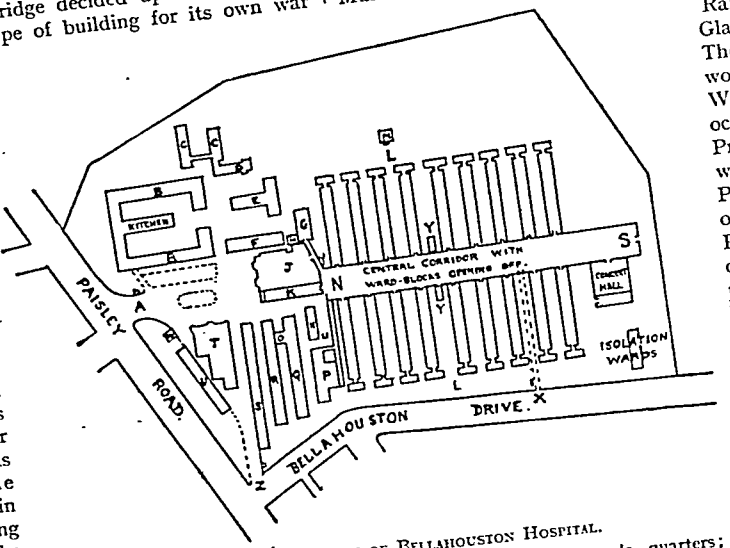
Scotland

Revision of the "British Pharmacopoeia"

At the third meeting for the session of the Pharmaceutical Society of Great Britain, held in the Society's Hall, York Place, Edinburgh, Mr. David Harley opened a discussion on the report of the Pharmacy Subcommittee of the British Pharmacopoeia Commission. The risks, he said, arising from the crystallization of the official liquefied carbolic acid during the cold weather could be obviated by the addition of 5 per cent. glycerin. A concession had recently been granted by the commissioners of Customs and Excise in regard to the use of industrial spirit by pharmacists in the making of pharmaceutical preparations, such as certain medicinal liniments. He suggested that in official formulae no purpose was served by requiring the use of highly expensive rectified spirit in preparations which were equally effective when made with the cheaper industrial spirit. He criticized the recommendation of the Revision Committee that for economical reasons olive oil should be replaced by cotton-seed oil, and suggested that, as olive oil was nowadays used both as a medicinal agent and as a food quite as much as cod-liver oil, the *Pharmacopoeia* should include tests and standards for the finest edible olive oil. In regard to the proposal to alter the composition of the familiar Gregory's powder, which was peculiarly a Scottish medicinal remedy, he said that in Scotland they would prefer that this preparation should be left alone. He approved of the suggestion to introduce an official formula for the compound syrup of iron phosphate, popularly known as Parrish's syrup or chemical food, but he thought that the formula proposed was unsatisfactory.

The Bellahouston Central Corridor System

The Scottish National Red Cross Hospital at Bellahouston, Glasgow, has lately been closed and dismantled, after having done service for fifteen years. Some 15,000 cases of sick and wounded in the war were treated there. Since 1919 it has been under the management of the Ministry of Pensions, to which department it was handed over by the Scottish Branch of the British Red Cross Society. Before it is allowed to lapse into its honourable history some practical lessons which it has afforded in hospital construction may be recorded. These were the subject of an article by Sir George Thomas Beatson in the *Glasgow Herald* of January 10th. Bellahouston Hospital was one of the first examples of the central corridor and one-story bungalow system of hospital construction. In Germany, in 1914, the Rudolf Virchow Krankenhaus, with 1,000 beds, was completed, and was in the form of single-story pavilions, which could be rapidly and economically duplicated as necessary. Immediately after the war broke out, Cambridge decided upon the central corridor and bungalow type of building for its own war hospital. In 1915 the Scottish Red Cross Committee resolved to erect a large general hospital quickly and economically, and in a manner which permitted of expansion to meet what even then seemed likely to be a prolonged and increasing need. After inspection of the war hospital at Cambridge, the central corridor plan with single-story wards leading off the corridor on each side was adopted for the Glasgow site, certain small changes being necessary to meet the northern climatic conditions. The value of such an arrangement, dispensing as it does with lifts and staircases, is apparent. Asbestos sheeting was chosen as the building material. The main lines of the construction followed at Bellahouston will be evident from the accompanying plan. The central corridor ran north and south, with nine one-story bungalow wards running off it on each side, sufficient space being left between the wards to permit of beds being wheeled out into the open air. Each ward contained fifty beds, and was complete in itself, with six small rooms at the end nearest the corridor for the use of the sister in charge, for special cases, and for other purposes; the sanitary arrangements for the ward were at the other end, completely shut off by a short passage with cross-ventilation. The central corridor had the additional advantage of affording two entrances to the hospital, at one end for the members of the staff and for the admission of patients, and at the other, for patients' friends. The other buildings, grouped chiefly to the north of the central corridor and the wards, included the receiving block, opening directly on to the corridor, a general and a small operating theatre, also of easy access, a large building for baths, massage, electricity, and radiant heat, orthopaedic workshops, and the administrative and pathological blocks. At a short distance were separate quarters for the doctors, the matron, and the nurses. Dining, kitchen, and recreation blocks were provided, and in the grounds at the other end of the hospital were the isolation wards. The hospital began with 500 beds, and subsequently increased its accommodation to 1,200 beds by means of seven additional blocks. This extra provision was made without interfering with the work of the hospital, and at a minimum cost. Had it been necessary, as the plan shows, further enlargement could have taken place to the south with the same expedition and economy. The plan reproduced has several points worthy of study—for example, the provision of store accommodation in rooms leading off from either side of the middle of the corridor. Sir George Beatson suggests that the memory of this famous hospital might fittingly be perpetuated by calling its plan of erection the "Bellahouston central corridor system."



PLAN SHOWING LAY-OUT OF BELLAHOUSTON HOSPITAL.

A, Main entrance; B and C, Nurses' quarters; D, Matron's quarters; E, Doctors' quarters; F, Administrative block; G, General operating theatre; H, Small operating theatre; J, Building for baths, massage, electricity, radiant heat; K, Receiving blocks; L, Ward blocks; M, Band-stand; N, Boiler house and destructor; O, Billiard room; P, Kitchen block; Q, Dining and recreation block; R, Orderlies' quarters; S, Hospital stores; T, Curative workshops; U, Pathological block; W, Garage; X, Entrance for patients' friends; Y, Nurses' cloakroom; Z, Entrance for stores.

Presentation to Professor Robert Muir

As intimated in this column last week, Professor Robert Muir was presented with his portrait in oils at a ceremony on January 20th in the Randolph Hall of Glasgow University. The portrait is the work of Mr. G. Fiddes Watt. On the same occasion a bust of Professor Muir, the work of Mr. G. H. Paulin, was handed over to the University. Professor Muir has occupied the chair of pathology at Glasgow University since 1899, having been transferred from the corresponding professorship in the University of St. Andrews. At one time he was pathologist to the Royal Infirmary of Edinburgh. Many contributors had subscribed to the gifts, including colleagues both in the University of Glasgow and in other pathological departments throughout the country, and past and present students. Principal R. S. Rait presided at the ceremony, and the presentation was made by Sir Frederick G. Hopkins, President of the Royal Society. Sir Frederick Hopkins remarked that the portrait was a gift which carried with it an expression of admiration, affection, and gratitude from Professor Muir's colleagues, pupils, and friends. Admiration was felt for his scientific work not only in this country, but in every centre where pathology was studied. The occasion, however, was not one of mere formality, but one which expressed affectionate feelings that were deeply rooted. Professor Muir had been a torch-bearer who had illuminated for many years the paths of progress in British pathology. The textbooks written by him had been an inspiration to multitudes of students, and many teachers had been grateful for them. Professor Muir's personal qualities of accessibility, sympathy, and generosity had created an atmosphere in his department which allowed his scientific vision and knowledge to have full play. He had created in Glasgow a centre of pathological thought and teaching which the speaker

believed was second to none in the world. Professor Muir, in accepting the gifts, expressed the high value that he placed upon these marks of regard. After reminiscences of his earlier days in Edinburgh, St. Andrews, and Glasgow, he said that one of the great attractions of pathology was an atmosphere of adventure, the possibility of doing something that had not been done before. It was a good thing that in pathology there was no such thing as authority. Another great attraction was that the pathologist could from time to time give help to surgeons and physicians, and was thus brought into contact with those who were combating suffering. He referred also to his predecessor, the late Professor Coats, whose great work for pathology, he said, would always be held in remembrance. Principal Rait accepted the bust on behalf of the University, and requested that it should be placed in the Western Infirmary, where most of Professor Muir's work had been done.

The Front Line Defence

At a recent meeting of the Public Health Committee of the Fife County Council, a discussion arose as to the need of regular co-operation between the public health staff and the general practitioners of the county. Ultimately it was resolved that conferences should be arranged from time to time with a view to frank interchange of opinions, but essentially to ensure the smooth operation of medical work in the area. This action of the committee is to be commended; as Bailie Primmer remarked, the general practitioners are the front line defence in the matter of public health.

England and Wales

Birmingham Women Medical Officers and the "Resignation on Marriage" Clause

Recently the Public Health Department of Birmingham City Council, in advertising for medical women for welfare work, inserted a clause requiring resignation from such appointments on marriage. Following upon a deputation representative of the National Council of Women and the Birmingham and District Medical Women's Association, however, the Maternity and Child Welfare Committee has decided not to insist upon that requirement.

Dame Ethel Shakespear, who introduced the deputation, reminded the committee that in 1921 the Birmingham City Council decided that married women should not be employed in its service, in view of the hardship which might be caused to men who were returning from the war and were anxious to obtain positions. An exception was made in the case of married medical women, and also of other women who, by virtue of their marriage, might be expected to do their work better than if they were unmarried. The recent advertisement of appointments for welfare work indicated apparently, said Dame Ethel Shakespear, that the committee had gone back on that policy, and the result would be, if it were persisted in, that married medical women would be pushed out of the public health service. The deputation and those it represented felt strongly that, as welfare work was one of the means of building up the family life of the nation, it was very desirable that there should be a leaven of married medical women among the officers in that service. Mrs. Wharton, chairman of the Citizenship Committee of the National Council of Women, said that such restriction as was now proposed would mean the loss to the service of the community of a number of women who would otherwise be of real value to it by virtue of their personal experience. She agreed that there might be cases where married women proved to be bad timekeepers, or failed to work properly on account of divided interests, but such persons could be winnowed out from employment. On the other hand, personal experience of parentcraft was a very great asset for the officer of a welfare centre. To the argument that long leave of absence would be necessary on the occasion of maternity, she urged that such leave should be granted in the same way as leave was occasionally granted to a medical man in order that he might perform a piece of work of national importance. No one could say that it was not work of national importance to bear a child, and the work of married medical women was sufficiently valuable for the city to justify the making of arrangements to cover such contingencies. The consequence of the marriage ban, added Mrs. Wharton, would be that if a woman was keen on her job, and knew that she would lose it on marriage, she would remain unmarried, though fitted for marriage and motherhood, and this would be a loss to the community. It was also stated that many working women preferred to deal with a married medical woman. Mrs. W. A. Cadbury, while in no way disparaging the work done by unmarried medical women, felt that a certain number of married women on the staff of the infant welfare centres would result in still better work. Dr. Beatrice Webb said that if married women were penalized in the way now suggested it would mean that the best women in the profession would go into private practice, and not into the public health service.

After the Maternity and Child Welfare Committee had considered the views advanced by the deputation, the chairman (Councillor E. W. Salt) stated that the committee had reviewed the whole of the circumstances, and had decided to rescind its decision. Thus it would be open for women medical officers to retain their posts after marriage. Birmingham has twenty-four municipal welfare centres and five maternity hospitals and homes.

University of London Medical Graduates Society

At the invitation of Lord Riddell, president, and the board of the Royal Free Hospital, a conversazione and cinema exhibition for members of the University of London Medical Graduates Society was held on January 22nd in the Eastman Dental Clinic. The guests were received by the President of the society, Sir John Rose Bradford, Bt., P.R.C.P. After tea a large company proceeded to the lecture theatre, where an instructive and interesting exhibition of cinema films took place. In introducing two medical films, Mr. W. McAdam Eccles, honorary treasurer of the society, stated his belief that medical educational films were of real service. If, for instance, a student was shown an anatomical film before dissecting the body, he would know what he had to look for and the method of obtaining this view. Nothing, of course, could take the place of actual dissection, and if the film were shown again after dissection then the student would have had three mental impressions of the part, thereby enhancing the likelihood of a permanent picture. A film of the anatomy of inguinal hernia, produced and exhibited by the Kodak Company and passed by the American College of Surgeons, was run through the projector, Mr. Eccles making a commentary. Similarly, a film of an actual operation on an inguinal hernia was exhibited. Dr. Claremont, the director of the Eastman Dental Clinic, then demonstrated a series of lantern slides exhibiting the work of the clinic, and answered numerous questions thereon. Finally, a film of the corresponding clinic at Rochester, New York, was shown, indicating the very useful work performed for school children by the skill of trained women "dental hygienists." The annual London dinner of the society will be held on Tuesday, May 12th, at 7.30 p.m., at the Langham Hotel.

Ireland

Hospital Policy

At a general meeting of the Ulster Branch of the British Medical Association, held on January 15th, with Mr. Howard Stevenson in the chair, there was an attendance of over seventy to hear an address by Sir Richard Luce on the Hospital Policy of the Association. He said that the ideals of the policy were that hospitals should be utilized only for such cases as needed institutional treatment, and that they should be available for educational purposes, not only for students, but for the whole profession. Grouping of hospitals should be such that one large hospital would act as a centre for consultant work, and would serve a district provided with cottage hospitals, special hospitals, and other institutions working in conjunction with it. General practitioners should be able to treat in hospital those patients needing special nursing, but obviously the base hospital could not supply this need, which must be fulfilled by subsidiary hospitals. Out-patient departments were much abused, and their scope should be restricted chiefly to casualties and to cases recommended by general practitioners. The staffs of voluntary hospitals were being exploited, and should receive monetary recompense from the various contributory schemes which now constitute a considerable part of the revenue of these hospitals. Dr. J. Armstrong, whilst agreeing with much of this, disagreed on some points. He advocated decentralization of specialist service, a large part of which could be more adequately given by the general practitioner with adequate provision of suitable institutions and apparatus. He also condemned the voluntary hospital system. Professor R. J. Johnstone, in proposing a vote of thanks to Sir Richard Luce, stressed the impossibility of acquiring sound surgical judgement without devoting one's whole time to this branch; he doubted the principle of paying the staffs of voluntary hospitals. Dr. R. W. Leslie seconded the vote. Sir Richard Luce, in the course of his reply, said that specialists were more necessary than ever to-day, because the growth of knowledge in every field rendered it impossible for any individual to be proficient in more than one branch.

Diphtheria Immunization in County Wexford

In a report to the County Wexford Health Board, Dr. J. Bastible, county medical officer of health, states that ten cases of diphtheria had been notified since December 1st—two in New Ross urban area, five in New Ross rural area, and three in the Wexford rural area. The epidemic in New Ross, which was apparently due to an infected milk supply, had been controlled, and the urban council had adopted a scheme of immunization, which, if fully carried out, would rid the town completely of the disease. In view of the large number of cases in the rural area of New Ross, and the possibility of a fresh outbreak, he recommended the Board of Health to adopt a modified scheme of immunization for this area, which would include the immunization of 150 children in five schools—namely, Ballykelly, Aclare, Cushinstown, Mylerspark, Rathgarogue; and the immunization of 300 children under 5 years of age in the dispensary district of Old Ross and in the rural part of the dispensary district of New Ross. The cost, including the expense of immunizing children from New Ross rural district who are attending schools in the urban area, was estimated to be about £100. As the cost of treating one case of diphtheria in the county fever hospital is about £10, it was pointed out that if the immunization scheme prevented only ten cases of diphtheria it would have paid for itself. Dr. Bastible's recommendations have been adopted.

Correspondence

FAMILIAL INCIDENCE OF CANCER

SIR,—Your correspondent Dr. Griffith Evans, in the *Journal* of January 24th (p. 157), describes two very interesting cases of families in which there was apparently a very marked hereditary factor, and suggests the possibility of further investigation on these lines.

This is a subject which is now interesting a great many research workers, but I doubt very much whether any light can be thrown upon it by the investigation of the familial histories of human beings. In order to get any satisfactory proof, it is necessary to trace the various members of the family back through a number of generations. Unfortunately, it is very seldom possible to find out what the grandparents died of, much less what the great-grandparents died of. It is possible that general practitioners living in one area, who hand on their practices to their sons or relatives, might be able to trace such families, but I doubt if it could be done on any systematic lines owing to the comparatively long period lived by human beings. There is fairly strong evidence that there is a hereditary factor in cancer, but it would appear to concern only one particular organ. Thus cancer of the rectum may have a hereditary factor, but a person inheriting such factor would have no tendency to die of cancer of the stomach, cancer of the breast, etc. Of course, it might easily happen that a tendency to cancer in two organs might be inherited, but it is obvious that very careful tracing of the histories would be necessary if any useful figures are to be obtained. It has been shown recently that cancer supervenes on other simpler growths, which themselves have a familial tendency. One of the best examples is that of multiple adenomatosis of the colon. This condition has a very marked familial incidence, and at first it would appear that it is the cancer which is the hereditary factor, though really it is the adenomatosis. A similar state of affairs may easily occur in regard to cancer of other organs. In fact, we know that simple multiple adenoma of the stomach is a precursor to cancer of that organ, and Sir Lenthal Cheatle has brought forth proof that duct cancer of the breast supervenes upon duct adenoma.

A strain of mice has been bred in America the females of which develop cancer of the mamma in 90 per cent. of cases, but the males do not develop cancer. It would be of the utmost value if doctors would trace such cases as those mentioned by Dr. Griffith Evans, but the difficulty would be to get accurate records of the exact nature of the tumour.—I am, etc.,

London, W.2, Jan. 23rd. J. P. LOCKHART-MUMMERY.

SIR,—I am indebted to Dr. Griffith Evans for directing my attention to an ambiguous reference to "cancer families" in my review of "The somatic cell mutation theory of cancer" in the Ninth Scientific Report of the Imperial Cancer Research Fund. We have good evidence for believing that a special type of cancer runs through certain families. I have referred specially to Dr. C. Dukes's work on polyposis intestini, that indicates the inheritance of "a tendency to epithelial proliferation leading to polypi and later to carcinoma."

My statement concerning cancer families was not intended to throw doubt upon the accuracy of the observations that have been recorded, but rather upon the validity of the conclusions which have been drawn from them upon the hereditary transmission of cancer. On the basis of chance distribution throughout the whole population there will be a certain number of families

in which the incidence of cancer will be relatively high, just as there will be families where little or no cancer will occur. This aspect of the cancer problem was discussed by the late Dr. E. F. Bashford in the Twelfth Annual Report (1914, p. 16) of this institution.—I am, etc.,

Imperial Cancer Research Fund, Queen Square, W.C., Jan. 26th. R. J. LUDFORD.

THE DIAGNOSIS OF SPECIFIC FEVERS

SIR,—Dr. Russell Brain's excellent lecture on zoster, varicella, and encephalitis (January 17th, p. 81), suggests that the time is opportune, as well as seasonable, for a spring-cleaning of our conceptions of specific fevers, conceptions which have not altered materially, perhaps, since the time of Sydenham.

We all know that the diagnosis "influenza" covers a multitude of divers infections, and the same may be true to a less degree of scarlet fever, German measles, and even chicken-pox, as it seems very probable that a number of cases due to different infective agents are now officially classed under one or other of these headings. Travelling round South Devon I often notice epidemics which, from the symptoms and the date of their appearance, are obviously the same, and yet, in different localities, receive different diagnoses. As an instance, some months ago a school epidemic, accompanied by a punctate erythematous rash, was diagnosed in one large town as rubella, although there was not the usual glandular enlargement, and although one case I knew of had had rubella within the year. In another locality the epidemic was called scarlet fever, and in yet another fourth disease. Probably there are other different epidemics accompanied by various erythematous rashes which might be labelled fifth, sixth, or seventh disease, and Dr. Brain rightly suggests that varicella may be due to more than one causative organism.

The prinicple I would like to emphasize is perhaps still insufficiently recognized—namely, that similar skin eruptions may be due to many different agents. Perhaps erythema nodosum may be quoted as an outstanding example; and no doubt the same is true of other organic manifestations, such as encephalitis, which may occur in mumps, measles, vaccinia, rubella, varicella, and variola. Practitioners who meet these appearances in the home under varying circumstances realize, better perhaps than the fever hospital staff, the difficulties of the position.—I am, etc.,

Paignton, Jan. 26th. ERNEST WARD.

ENTERIC INTUSSUSCEPTION

SIR,—I note in the *Journal* of January 10th (p. 58) a memorandum by Mr. Robert Glover on enteric intussusception. In my experience this is not so uncommon as he appears to think. During the past six years I can recall four cases.

Case 1.—A woman, aged 35. Admitted to hospital with acute appendicitis; appendicectomy without drainage; convalescence normal until the sixteenth day, then some indefinite signs of intestinal obstruction. On the eighteenth day after operation my house-surgeon telephoned to say he could "feel a lump, and thought I had left a swab in the abdomen." Operation showed an irreducible ileal intussusception, involving about five feet of ileum. This was resected, and end-to-end anastomosis performed. Recovery was uneventful; cause of intussusception unknown.

Case 2.—Male, aged 28. Admitted with two days' history of subacute obstruction. Lump felt, and intussusception diagnosed. Operation confirmed this. Site was the lower ileum, and the intussusception was irreducible; excision and end-to-end anastomosis performed. Unfortunately, on the sixth day, signs of peritonitis occurred, and he died the next day. Post mortem, a Meckel's diverticulum was found two feet beyond the resection. Doubtless this had caused the intussusception, and subsequent to the resection had thrown too much pressure on the anastomosis by chronic obstruction, and resulted in the leak at the site of anastomosis which had given rise to the peritonitis.

Case 3.—A woman, aged 40. History of subacute obstruction of three days; an irreducible ileal intussusception found. Resection with end-to-end anastomosis performed. Recovery. No cause for intussusception discovered.

Case 4.—A man, aged 31. Admitted to hospital suffering from acute obstruction. A tumour was felt just below and to the left of the umbilicus. Laparotomy showed an irreducible intussusception of the ileum. About four feet of intestine were involved. Resection and end-to-end anastomosis were performed. Uneventful recovery. Examination of the excised ileum showed the cause of the intussusception to be a small polypus at the head.

My experience of enteric intussusception is that it is the commonest type in adults, and that it speedily becomes irreducible.—I am, etc.,

Bradford, Jan. 15th. COLIN MACKENZIE.

MANAGEMENT OF THE PUERPERIUM IN TUBERCULOUS WOMEN

SIR,—In the discussion on the management of pregnancy, parturition, and the puerperium in tuberculous women, reported in the *Journal* of January 24th (p. 140), I find no mention of an item which I have found by experience to be of great importance. While women suffering from pulmonary tuberculosis usually improve during pregnancy, there is a great tendency to renewed activity of the disease after the termination of pregnancy. This tendency can be best combated, and usually successfully, by keeping the patient in bed for a month after her confinement, even though the temperature be normal.—I am, etc.,

Belfast, Jan. 26th. JOHN R. GILLESPIE.

TREATMENT OF ETHMOIDITIS

SIR,—Like your correspondent Mr. J. F. O'Malley, I was unable to appreciate any special factor indicative of safety in the suggestions put forward by Mr. Peters in his paper in the *Journal* of January 10th. Much of the confusion of thought and practice which surrounds this important surgical operation would be dispelled if the following principles were clearly realized and acted upon.

1. The maxillary antra, ethmoid, and sphenoid sinuses should be each explored with suitable trocar, cannula, and glass syringe under general anaesthesia as a preliminary to whatever form of nasal sinus operation is to be carried out.

2. Not only the presence of pus or muco-purulent flakes in the fluid brought back in the syringe, but the return of a viscid fluid, is indicative of one or other form of chronic sinus disease.

3. Scrupulous precautions should be taken to ensure that the nasal sinus inflammation is absolutely *à froid* at the time the operative intervention is carried out.

4. Whilst infection of the maxillary antrum is the responsible factor in the majority of these cases, a plurality of infected sinuses is very often present, the contiguous ethmoidal cells being the most frequently involved, in my opinion, from secondary infection.

5. The surgeon should duly and adequately respect the "danger area"—namely, the area which, according to Burger, is limited by the perpendicular plate of the ethmoid within, the cribriform plate above, and the inner surface of the middle turbinal without.

6. All diseased sinuses on one side, or eventually on both sides, of the nose should be surgically treated at one operation.

7. The removal of the middle turbinal, if requisite, should be deferred to the very end of the operative intervention, and this removal should be effected by a clean cut with a von Struychen forceps followed by the use of a snare as suggested by Mr. O'Malley.

The observance of the "respect" alluded to in paragraph 5 is not consonant with Mr. Peters's statement that "removal of the middle turbinal by Luc's forceps should be carried out either in its entirety by gripping the body of the bone, or by 'nibbling' from the anterior end and removing the opened cell." The writer considers that the use of the instruments and methods of the late Dr. Sluder in this area must constitute a dangerous, as well as a quite unnecessary, procedure. In all cases of multiple sinus disease in which the frontal sinus can be excluded—and this group constitutes the big majority—it is my practice to take down the outer wall of the diseased ethmoidal labyrinth and, if necessary, the anterior wall of the sphenoid sinus with a Luc's forceps operating from the canine fossa and across the antrum, after this cavity has been dealt with in the conventional manner. This method, which I have described in detail in the *Journal of Laryngology and Otology* (August, 1926), and which I have employed frequently for over eight years, is extremely safe and rapid, and allows the operator to open up all cells within the ethmoidal capsule, including the agger and fronto-nasal cells, without any encroachment upon the danger area. The actual removal of diseased tissue is carried out by Moure's hooded scoops, which are worked from behind downwards and forwards, and which by their shape preclude injury to the overlying orbital plate. The removal of the middle turbinal, which is rarely required, would constitute the final step of the operation.

In cases of concomitant frontal sinus disease in which the latter requires operation, I carry out the Howarth operation, which best allows the observance of the principles I have enumerated above.—I am, etc.,

Cork, Jan. 26th. J. B. HORGAN.

CINCHONA AND QUININE

SIR,—It is with some diffidence that I offer the following information with reference to the article on cinchona febrifuge (*Journal*, December 6th, 1930, p. 969), because the facts referred to, although quite clear in my own memory, cannot be substantiated by figures, since the papers were all eaten up by white ants between 1914 and 1918. Previous to the former date I was civil surgeon in the Bhamo district, and the hospital budget for medicines for a 64-bed hospital was only Rs600 (about £40) per annum. We used to have a lot of malaria in the hospital, and quinine sulphate was selling at Rs16 per pound in those days. The Inspector-General brought to my notice a preparation produced in the Neduvattam cinchona factory known as "amorphous cinchona alkaloid," which was being sold at Rs4 per pound. I tested a series of cases, the even numbers being put on quinine sulphate and the odd numbers on amorphous cinchona alkaloid. The result showed that it was possible to break the periodicity of the paroxysm with an equal weight of the latter as compared with the former after an equal interval, and that a period of continued antimalarial treatment with equal weights of the latter was as efficient as with the former; in other words, the cost of cure was reduced to one-quarter of the previous cost.

Subsequent experience has led me to give up entirely the use of all the salts of quinine except the hydrobromide, which can be employed to break the periodicity of the paroxysm with the least possible discomfort to the patient; thereafter the use of "Tabloid" tr. cinchonae co. has given results which have been uniformly successful, the cost being proportionately less.—I am, etc.,

L. A. HODGKINSON LACK,
University of Rangoon, Jan. 5th. Lieut.-Colonel I.M.S.

TREATMENT OF VARICOSE ULCERATION

SIR,—Every single one of your correspondents on the subject of the Dickson Wright treatment for chronic ulcer of the leg has missed the point in such a way that it is almost incredible that they can have read the papers on this subject published in the *Journal* of December 13th, 1930.

The method does not depend on firm support of the leg by bandaging, and it is evident that if it did it would have little advantage over the traditional methods mentioned by your correspondents. At the risk of becoming tedious by repetition I would point out again that it is necessary to compress or squeeze the excess tissue fluids out of the limb, where they are stagnant by virtue of (*a*) gravity, (*b*) 120 mm. Hg of arterial pressure, and (*c*) 48 inches of blood in the superficial veins (less any surplus capacity in the deep veins). Firm support will no doubt prevent further accumulation, but, in the absence of some such arrangement as described by Dr. Moulden, it will not get rid of that which is there already. To accomplish this the bandage must be wound on tightly—often, indeed, as tightly as a strong man can pull without tearing the bandage.

Naturally fear and superstition, more politely known as the first principles of surgery, will deny the 100 per cent. results we have obtained to many who have not the courage to follow our directions literally.—I am, etc.,

Hove, Jan. 19th. J. H. TWISTON DAVIES.

MEMBERS OF THE ROYAL COLLEGE OF SURGEONS

SIR,—The negative reply given by the Council of the College, reported in your issue of January 17th, to the request of the Members for *some* representation on the Council, has filled one with consternation. The one point that had been emphasized by the President himself, and by preceding Presidents—that there was no proof that the bulk of the Members were in favour of this representation—has been more than refuted by the result of the poll.

The string of the functions of the College given in the report are, as stated, "well carried out." Who has questioned this? The answer is that the functions, correct as they are, do not go far enough. Those Members that have had to bear the full responsibility of country practice in regions remote from hospitals and nursing homes, and who have been compelled to carry through operations of moment under extreme adverse conditions, patients refusing to be treated in any other place than in their own cottages, feel that they have a moral right to have some representation on a Council that functions for the surgical branch of our profession in this country. The "advancement of surgery in its widest sense," as stated in the report, is therefore not covered.

John Hunter, the virtual founder of the College, would, in my opinion, have taken a different view of the case. Had this passionate pioneer been alive to-day, we can picture him having not a little to say to those "die-hard" members of the Council that are still encircled and protected by their stone-wall method of defence. *Summum jus, summa injuria*!—I am, etc.,

Crouch End, N.8, Jan. 24th. T. WILSON PARRY.

Obituary

FREDERICK MEADOWS TURNER, M.D., B.Sc., D.P.H.

Medical Superintendent, South-Eastern Hospital, London County Council

We regret to record the death, at the age of 64, of Dr. F. Meadows Turner, which took place on January 17th, following an operation on January 12th. He was born in China, the son of a missionary, but came to England at an early age and received his medical education at Trinity College, Cambridge, Guy's Hospital, and Heidelberg. He took his B.Sc. degree at London University in 1887, and two years later his B.A. degree at Cambridge, where he graduated M.B., B.Ch. in 1892 and M.D. in 1895. On qualification in 1892 he was appointed a house-physician at Guy's Hospital, and in the same year entered the fever service of the Metropolitan Asylums Board. After being assistant medical officer under Dr. E. W. Goodall at the Eastern Hospital and at the North-Eastern Hospital under the late Dr. R. A. Birdwood, and acting as medical superintendent at the Hospital Ships and Gore Farm Hospital, he was appointed, in 1896, medical superintendent of the South-Eastern Fever Hospital, New Cross, where he remained in office until his last illness. He had been due to retire next August, on reaching the age limit.

Dr. Turner possessed in a high degree a mathematical ability which aroused the admiration and envy of his less gifted colleagues, and admirably fitted him for dealing with the statistical problems arising in the course of his work. For many years he rendered valuable service by acting as one of the two editors of the Medical Supplement of the Metropolitan Asylums Board's Annual Reports as well as by being a frequent contributor thereto of papers on clinical and statistical subjects. The medical profession is especially indebted to him for the immense amount of labour spent in the compilation of the summary in the 1910 report of all the tables published in the reports for the years 1900–9 inclusive. His principal contributions to medical literature were his M.D. thesis, published in 1895 in vol. li of *Guy's Hospital Reports*, on scarlatinal nephritis and its varieties, a valuable clinical and pathological study based on his experience at the North-Eastern Hospital, and a review of the literature; a special report, published in 1906, to the Metropolitan Asylums Board on return cases for the years 1902, 1903, and 1904, which formed an interesting sequel to the report made by Dr. A. G. R. Cameron in 1904; and a paper, inspired by Professor Karl Pearson, on the correlation between vaccination and small-pox in the London epidemic, 1901–2, and published in *Biometrika* in 1906.

His courses of instruction to students in the diagnosis and treatment of acute infectious diseases were always well attended. It is related that on one occasion he brought an inattentive and talkative class to their senses by suddenly saying, "Good afternoon, gentlemen," and leaving them shepherdless and bewildered in the ward. Unlike the medical superintendent of many fever hospitals Dr. Turner did not lead a sequestered life, but was attached to a number of medical societies. In addition to being a member of the Association of Physicians of Great Britain and the West Kent and the New Cross Medical Societies, he was a constant attendant of the Section of Epidemiology of the Royal Society of Medicine, and recently joined the Medical Superintendents' Society, which met at the South-Eastern Hospital shortly before his last illness. Dr. Turner's scientific interests were by no means confined to medicine. He was a member of the Queckett Microscopical Club and the Essex Field Club, and took a keen interest in fresh-water biology. He had for some time been paying special attention to the breeding of the common British freshwater mollusc *Limnaea peregra*, and was the joint author, with A. E. Boycott, C. Diver, and S. L. Garstang, of a paper recently published in *Philosophical Transactions* on the inheritance of sinistrality in *Limnaea peregra*. He had previously contributed papers on this mollusc to the *Naturalist* in 1926 and the *Essex Naturalist* in 1927.

Quiet and unassuming in manner, of a singularly equable disposition, readily accessible and helpful to all, Dr. Turner will be greatly missed, not only by the staff of his hospital, among whom he was known by the title of "Father," but by a wide circle of friends, many of whom had been his former pupils. The large gathering which attended his funeral, at Brockley Cemetery on January 21st, bore eloquent testimony to the affectionate esteem in which he was held. He is survived by a widow, but had no children.

Mr. WILLIAM ELSWORTH WARNE, who served the British Medical Association for forty years, and held the office of Financial Secretary and Business Manager from 1918 to 1921, died on January 26th at the age of 74. Members of Council, and many others who in former years took part in the central work of the Association, will share the regret felt by senior members of the headquarters staff at the passing of an old friend and a loyal colleague. Mr. Warne's upright character and kindly disposition won him the respect and affection of his fellow workers. His connexion with the Association began in 1881, when the membership was little more than 9,000, as compared with 23,000 when he left its service. On the occasion of his retirement ten years ago the Council presented to him an illuminated address, placing on record its grateful appreciation of his faithful and untiring work for the Association as clerk, chief clerk, and finally Financial Secretary and Business Manager in succession to the late Mr. Guy Elliston. The Chairman, Sir Robert Bolam, in making the presentation, said that the Council's wish was to show to Mr. Warne in this way that his devotion to the interests of the British Medical Association was recognized as setting an example to all those who tried to make that great Association a power for good in the profession and the community. Throughout his long period of service they had admired, too, his unfailing courtesy and kindness to everyone around him. A presentation was also made to Mr. Warne by the staff at a complimentary dinner presided over by the late Sir Dawson Williams, Editor of the *Journal*. After his retirement from active work Mr. Warne continued to take an interest in the Medical Insurance Agency as a member of the board of management. The funeral took place at Fulham Cemetery on Thursday, January 29th.

The following well-known foreign medical men have recently died: Professor GEORG HONIGMANN of Wiesbaden, author of several works on medical philosophy, aged 66; Dr. ROCCO SANTOLIQUIDO of Milan, formerly president of the International League of the Red Cross, director-general of the Italian public health service, and Grand Officer of the Legion of Honour, aged 76; Dr. RAYMOND SEYER, a prominent physician of Rouen; Dr. N. JANCSO, professor of internal medicine at Debreczen, aged 61; Professor E. SAVINI, a prominent Rumanian neurologist, aged 48; Dr. BELLOM PESCARDO, a neurological surgeon of Turin, aged 69; Dr. PIERRE DESCOMPS, surgeon to the Charité Hospital, Paris; Dr. PAUL SIMON, honorary professor of clinical medicine in the Nancy Medical Faculty; Dr. WILLIAM CRAIG, emeritus professor of surgery in the University of Colorado School of Medicine, aged 75; and Brigadier-General JAMES MADISON KENNEDY of the United States Army, aged 64.

Medico-Legal

INJURY TO PATIENT IN NURSING HOME

ALLEGATIONS OF NEGLIGENCE

Before Mr. Justice McCardie and a special jury on January 20th and 21st an action was heard in which Mrs. Elizabeth Collins, a widow of Llandudno, claimed damages for alleged negligence from Miss Sarah Froggatt, proprietress of "St. Helen's" nursing home, Llandudno, Dr. Edith Annie Shaw of Colwyn Bay, and Dr. Anna Gwenllian Lewis of Rhos-on-Sea. Miss Froggatt admitted negligence, but Dr. Shaw and Dr. Lewis denied it, and Dr. Shaw counterclaimed £200 for fees due to her from Mrs. Collins, being £37 for fees for an operation, and the remainder fees for attendance in connexion with a burn received by the patient, which was the subject of the action.

Mr. Norman Birkett, K.C., in opening the case for the plaintiff, said that in February, 1929, Mrs. Collins underwent an operation at the nursing home, Dr. Shaw performing the operation and Dr. Lewis administering the anaesthetic. After the operation the patient was removed to a bedroom on a stretcher, and, later, it was discovered that she had been laid, while unconscious, on a rubber hot-water bottle, which had caused an extensive burn. The plaintiff suffered great pain in consequence, and was still partially disabled. It appeared that a maidservant, under the direction of the nurse, had placed the bottle in the bed which the patient was to occupy, and, being under the draw-sheet, it was not noticed when the stretcher was laid thereon. Mr. Birkett said that the anaesthetist, who was responsible for making the patient unconscious, had the duty of taking all reasonable care to guard the patient against such a peril as that encountered by the plaintiff during unconsciousness, and the surgeon who performed the operation in the circumstances of the present case was also bound to see that the patient sustained no injury. It was not enough for either of them to say that the patient was left to the care of the nurse.

Mrs. Collins, in evidence, said that the nursing home was a house of four or five bedrooms, one of which—not a special operating theatre—was used for the operation. The burn was about 2 ft. by 1½ ft. in extent, and, nearly two years afterwards, the part was still painful, and prevented comfortable seating or lying on the back. She agreed that Miss Froggatt had been anxious to do all she could for her, and had not sent in any account for services rendered, also that she had had Dr. Shaw to attend her for a year after the operation. The nurse also stated that after the accident Miss Froggatt refused to have other patients in the home, and devoted her whole time to looking after Mrs. Collins. Professor Leonard Gamgee of Birmingham University said that the plaintiff had a deep burn over the bone at the extreme end of the spine and across the buttocks. He was astonished at the depth of burn received from a hot-water bottle. Eighteen months after the accident the wound had healed except for a space of about three square inches. There was thick and dense scarred tissue over the right buttock, which interfered with the patient's movements and capacity to sit down.

After consultation between judge and counsel, Mr. Birkett announced that a settlement had been reached. Miss Froggatt had admitted negligence, and had paid £600 into court. Plaintiff now sought judgement for that sum and an agreed sum for costs. The two medical defendants were in a different position. There was never any allegation of negligence against them at any stage or at any time in that case so far as their professional skill was concerned, and had Professor Gamgee completed his evidence he would have said that the operation had evidently been conducted with the highest skill and judgement on the part both of Dr. Shaw and Dr. Lewis, and that the devoted attention of Dr. Shaw had contributed in a very large measure to the recovery in body and mind of the plaintiff. The allegation of negligence in the case so far as the doctors were concerned was that in the particular circumstances a particular duty rested on the surgeon and the anaesthetist, but having regard to the evidence, he had advised the plaintiff that she would not be able to substantiate that allegation, and it would be completely withdrawn.

Mr. Roland Oliver, K.C., for Dr. Shaw, in asking for judgement for the amount of her counterclaim with costs, said that his client had always been willing, as she was still, to give up the whole of that amount, including the operation fee, on the understanding that the money was paid to the plaintiff, and that the plaintiff was not in any way mulcted in regard to costs. Dr. Shaw would not seek to recover her costs against anybody, on account of her sincere sympathy with the plaintiff. That was a voluntary action on the part of the defendant, and did not involve in any degree any sense of bargain, or anything of the kind. Mr. J. Singleton, K.C., asked for judgement for Dr. Lewis, and stated that she, too, would not seek to enforce against the plaintiff, having regard to the withdrawal of the allegation.

Mr. Justice McCardie said that he was glad the parties had reached a satisfactory settlement. Dr. Shaw and Dr. Lewis, it was now agreed, were free from any suggestion of negligence, and both had acted with skill, care, and judgement.

Judgement was then entered for the plaintiff for £600 and agreed costs against Miss Froggatt, and for the two doctors, on whose behalf it had been said that they would not enforce judgement.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons this week discussed the report of the Indian Round Table Conference and finished the second reading debate on the Trade Disputes Bill.

The Socialist medical group are to seek a conference with Mr. Greenwood on a projected Maternity and Child Welfare Bill.

Mr. Snowden stated, on January 27th, that the Government wishes to proceed with the Hours of Industrial Employment Bill. He could not say when the further stages of the measure would be taken.

The Prime Minister regrets that he cannot make any further statement with regard to the introduction of legislation to amend the Factory Acts.

Pharmacy and Poisons Bill

In the House of Lords, on January 27th, Earl RUSSELL moved that the second reading of the Pharmacy and Poisons Bill, which had been put down for that day, should be postponed *sine die*. He explained that the second reading could not be taken that day. He understood that a great many people were interested in the measure, but he was not able at present to name a day when it would be taken. He therefore proposed to let the Bill remain on the Order paper, and he would give as long notice as possible of the day when it was proposed to take the second reading. The motion was agreed to.

Tuberculosis Statistics

Mr. GREENWOOD, replying to Dr. Fremantle on January 22nd, said that in 1915 there were 68,309 new cases notified in England and Wales and 40,803 deaths from pulmonary tuberculosis, and 22,283 new cases notified and 13,492 deaths from non-pulmonary tuberculosis. These figures had dropped by 1929 to 57,274 new cases notified and 31,425 deaths from pulmonary tuberculosis, and 18,682 new cases notified and 6,565 deaths from non-pulmonary tuberculosis. Dr. FREMANTLE asked whether the Minister deemed this evidence requiring urgent action. Mr. GREENWOOD said he did not think so. Both new cases and deaths showed a pretty substantial decline. He could give no classified information concerning the number of cases attributable to infection of bovine origin.

Spahlinger Treatment of Tuberculosis

In reply to Mr. Mander, on January 22nd, Mr. GREENWOOD said that no experiments had been, or were being, carried out in connexion with the Spahlinger treatment of tuberculosis by or in co-operation with his Department. He was aware that experiments in connexion with this question were

being carried on in Northern Ireland at the present time. Other experiments were being carried out in co-operation with the Ministry of Agriculture in Great Britain.

Social Services

On January 23rd Mr. BRACKEN asked whether the considered policy of the Government was represented by a recent declaration by the Minister of Health that he would not consent to any reduction in social services. Mr. RAMSAY MACDONALD, in reply, said that the Government would not regard a contraction of efficiency in social services as a desirable form of national economy.

Mr. GREENWOOD told Captain Peter MacDonald, on January 22nd, that the arrangements with regard to the State maternity service were not sufficiently advanced for him to make any statement on the possibility of any reduction of the cash benefit for mothers.

Public Cleansing in London

Answering Dr. Fremantle, on January 22nd, Mr. GREENWOOD said that he understood that the Metropolitan Boroughs Standing Joint Committee had referred the report of the Departmental Committee on London Cleansing to the metropolitan sanitary authorities. Their replies would be considered at a meeting of the Standing Joint Committee on January 26th. He was informed that two of the borough councils had entered into fresh contracts for the tipping of refuse on a new site under improved conditions. Dr. FREMANTLE suggested it would be well to prevent any action being taken independently. Mr. GREENWOOD answered that he hoped it was not suggested that he should prevent enlightened authorities from making better provision. Dr. FREMANTLE then asked if Mr. Greenwood did not wish the report of his Department, which required a centralized authority, to be carried out. Mr. GREENWOOD said that he wanted the report to take effect, but it would involve highly controversial legislation.

Maternity and Child Welfare

On January 20th Mr. HOLFORD KNIGHT gave notice that, on going in committee of supply on the Civil Service Estimates, he would call attention to the question of maternity and child welfare, and move a resolution.

Housing.—Mr. GREENWOOD told Mr. Albery on January 22nd that since the armistice approximately 11,000 houses had been demolished under improvement and reconstruction schemes undertaken by local authorities in England and Wales. The 224 local authorities which had so far submitted programmes under the 1930 Housing Act proposed to demolish approximately 60,000 houses in clearance and improvement areas during the next five years.

Meat Inspection.—Replying to Mr. Samuel on January 22nd, Mr. GREENWOOD said the recommendation which for many years had been made by his Department to local authorities and generally adopted at the ports was that where there had been evidence or suspicion of caseous lymphadenitis in imported mutton and lamb, the whole carcass should be destroyed. The desirability of taking steps so that legs, shoulders, sides, saddles, and other parts of mutton and lamb should be passed by medical officers before the meat was shipped was receiving his consideration.

A Bill Talked Out.—On January 23rd Mr. KELLY moved the second reading of the Spiritualism and Psychical Research (Exemption) Bill. Dr. FREMANTLE moved its rejection. He said that the Bill proposed to relieve spiritualists and mediums from any penalties the law had thought fit to place on them. Spiritualism had been associated with a perversion of the uninformed mind of the young, and had disastrous effects in many cases. The law protecting people from such misguidance should not be remitted. The Bill was talked out.

Notes in Brief

The Home Secretary will consider a modification in the present law in respect of the trial of a pregnant woman on a capital charge.

No fresh outbreaks of foot-and-mouth disease had occurred in any part of Great Britain since that confirmed on January 18th at Westmeston (Sussex). The source of infection in that case had not been discovered.

Universities and Colleges

UNIVERSITY OF OXFORD

The following candidates have been approved at the examinations indicated:

FINAL B.M., B.CH.—A. H. Bateman, F. Bell, R. T. V. Clarke, F. R. Crookes, H. R. J. Donald, H. C. Harley, R. S. Harrison, M. A. Hatt, J. M. Lees, R. D. Newton, N. C. Parfit, W. G. Rees, E. H. Rink, B. T. Squires, F. M. Trefusis. (*Materia Medica*) C. F. S. Alken, E. J. Baldwin, S. W. T. Bentall, J. A. Boycott, L. G. Clayton, J. M. Cribb, T. T. Hardy, J. L. Ryce, O. S. M. Williams. (*Pathology*) E. J. Baldwin, S. W. T. Bentall, R. R. Bomford, E. Braithwaite, F. W. Brown, N. P. Bruce, H. W. Davies, R. C. Garman, H. F. Moseley, J. A. Nunn, T. R. Plummer, T. W. H. Porter, J. L. Ryce, A. E. Scott, J. A. E. Scott, H. C. Wadge, E. J. Williams, C. H. Yeoh. (*Forensic Medicine and Public Hygiene*) E. J. Baldwin, D. S. Bateman, A. H. Bateman, R. R. Bomford, N. P. Bruce, J. M. L. Burtenshaw, F. R. Crookes, T. M. Davie, H. W. Davies, N. Heath, J. H. Hunt, K. N. Irvine, H. de B. Kempthorne, R. M. Marshall, Q. St. L. Myles, M. W. C. Oldfield, W. G. Rees, E. H. Rink, B. T. Squires, Olive M. Capper Johnson.

Mr. W. D. W. Brooks, B.A., M.R.C.S., formerly a scholar of the College, has been elected to a Fereday Fellowship at St. John's.

At a congregation held on January 22nd the following medical degrees were conferred:

D.M.—P. N. B. Odgers, P. L. Gibson.
B.M.—B. T. Squires, R. T. V. Clarke, W. G. Rees, Mrs. Rosalind V. Ferguson.

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE

A course of five lectures on "The modern technique of cytology" will be given at University College, Gower Street, by Professor R. Chambers, Dr. R. G. Canti, and Dr. R. J. Ludford, on Fridays, at 5 p.m., beginning to-day (January 30th) and ending on February 26th. The lectures are open without fee to students of the University and others interested in the subject.

A course of three lectures on growth problems in plants will be given at the Imperial College, Royal School of Mines, Prince Consort Road, S.W.1, by Dr. F. G. Gregory, on Tuesdays, February 10th, 17th, and 24th, at 5.30 p.m. Admission free, without ticket.

UNIVERSITY OF MANCHESTER

Professor H. S. Raper, M.B., F.R.S., has been appointed Pro-Vice-Chancellor of the University in succession to Professor Kastner.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

The degrees of M.B., B.Ch., B.A.O., and B.A. were conferred upon R. E. Hemphill on January 16th.

The Services

DEATHS IN THE SERVICES

Major William Gordon Wright, D.S.O., R.A.M.C., died at the military hospital at Murree, in the Punjab, of pneumonia, on October 15th, 1930, aged 47. He was born on June 22nd, 1883, and was educated in Dublin, taking the L.R.C.P. and S.I. in 1906. After filling the post of resident surgeon at the Adelaide Hospital, Dublin, he entered the R.A.M.C. as lieutenant on August 1st, 1908, received a brevet majority on January 1st, 1919, and was promoted to major on August 1st, 1920. He served throughout the war of 1914–18, when he was three times mentioned in dispatches, in the *London Gazette* of February 17th, 1915, June 15th, 1916, and January 4th, 1917, and received a brevet of major and the D.S.O. He leaves a widow.

Lieut.-Colonel Isaac Bomford Emerson, R.A.M.C. (ret.), died at Bath on November 4th, 1930, aged 77. He was born in Dublin on December 17th, 1852, was educated in Dublin, and took the L.R.C.S.I. in 1873 and the L.K.Q.C.P. in 1874. Entering the Army as surgeon on February 4th, 1877, he became lieutenant colonel after twenty years' service, and retired on December 17th, 1907. He served with the 83rd Foot, now the Royal Ulster Rifles, in the Afghan war of 1878–79, receiving the medal, and was also re-employed at home, from October 26th, 1914, in the war of 1914–18.

Medical News

Two lectures, on the national diet, will be given by Professor E. P. Cathcart, at 6 p.m. on February 23rd and 24th, at the London School of Hygiene and Tropical Medicine, Gower Street. Admission is free, without ticket.

A special discussion on "The adaptation of European women and children in tropical climates" will be held at a joint meeting of the Sections of Tropical Diseases and Parasitology and of Disease in Children of the Royal Society of Medicine, to be held on Thursday, February 5th, at 8 p.m.

At a meeting of the British Institute of Philosophical Studies, to be held at University College, Gower Street, W.C., on Tuesday, February 3rd, at 8.15 p.m., a lecture on "Purpose in evolution" will be given by Sir Arthur Thomson, with Dr. J. S. Haldane, C.H., F.R.S., in the chair.

Under the auspices of the British Empire Cancer Campaign (Yorkshire Council) and the Leeds and West Riding Medico-Chirurgical Society, Dr. Ronald G. Canti, bacteriologist to St. Bartholomew's Hospital, will give a cinematograph demonstration of living-tissue cells growing *in vitro*, with special reference to cancer, at the Alexandra Picture House, Camp Road, Leeds, on Wednesday, February 4th. The chair will be taken at 3.30 p.m. by Professor M. J. Stewart.

At the opening of the ninetieth course of study at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Tuesday, February 3rd, Dr. P. Manson-Bahr will give a lecture and lantern demonstration on "The dawn of tropical medicine," being an account of the life and work of Sir Patrick Manson. The chair will be taken at 5 p.m. by Sir Harry Goschen, Bt. Admission is free, without ticket.

In the absence, through illness, of Dr. T. Watts Eden, President of the Royal Society of Medicine, the guests at the society's reception on the evening of January 21st were received by the immediate Past-President, Lord Dawson of Penn, and Lady Dawson. The announcement that Dr. Eden was now well on the way to complete recovery dispelled the only cloud over the gathering. The Barnes Hall was filled for a short illustrated lecture by Dr. Arnold Chaplin on "Some great figures in history." Having on previous occasions taken his audiences, as he said, down the narrow path of medical history, he confined himself on this occasion to certain celebrities who were renowned in other fields, his purpose being to remove some misconceptions which have clung to these characters.

The thirty-fifth Congress of French-speaking Alienists and Neurologists will be held at Bordeaux on March 27th, when the following subjects will be discussed: late periodic psychoses, introduced by R. Anglade of Vauclaire, Angoulême; spinal cord tumours, introduced by Noel Perron of Paris; and false simulation in mental disease, introduced by Fribourg-Blanc of Paris.

The German Society for Internal Medicine will hold its forty-third annual meeting at Wiesbaden, under the presidency of Professor von Bergmann of Berlin, from April 13th to 16th, when the following subjects will be discussed: neuroregulation, introduced by Goldstein of Berlin and Weiszäcken of Heidelberg; coronary circulation and angina pectoris, introduced by von Anrep of Cairo and Edens of Ebenhausen. A lecture will also be delivered by Bürger of Osnabrück on the clinical significance of the cholesterin problem.

The first Hispano-Portuguese Congress of Obstetrics and Gynaecology will be held at Madrid in April, under the presidency of Dr. Luis Soler Soto, president of the Spanish Gynaecological Society. Further information can be obtained from the general secretary, Dr. Francisco Haro, Serrano 74, Madrid.

With the object of making its natural advantages better known to members of the English medical profession, the authorities of Dax, a thermal resort situated in the Pau-Biarritz district of France, gave a dinner party at the Savoy Hotel, London, on January 26th. The chair was taken by Sir StClair Thomson, and among the guests were leading physicians and other medical men and women interested in hydrology and climatotherapy. The chairman gave the toast of the King and the President of the French Republic; and the health of the guests, proposed by M. Clement Bich, Administrateur de la Société Thermale de Dax, was responded to by the Consul-General for France. After these speeches, Dr. Leonard Williams entertained the company with a short discourse on the climate and waters of Dax and their therapeutic indications, followed by the exhibition of a cinema film. The arrangements for this very agreeable and informative evening were made by Mme Juppé-Blaise, manager of the Federation of the Health Resorts of France.

The Wellcome Museum of Medical Science is closed until further notice during rebuilding.

According to the monthly report of the Health Section of the League of Nations, 744,731 cases of scarlet fever were reported in Europe in 1929, as compared with 695,065 in 1928, and 667,222 in 1927. The increase in the incidence of the disease was most marked in Rumania, England, and Czechoslovakia, in the order named. A similar increase in diphtheria morbidity is shown by the fact that 27 European countries, which reported 257,959 cases in 1927 and 296,070 cases in 1928, recorded 327,391 cases in 1929.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecta Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Exfoliative Dermatitis

"J. A. H." asks for suggestions for the treatment, at home if possible, of a severe case of exfoliative dermatitis.

Treatment of Obesity

"A. S." asks for suggestions in the treatment of a female patient who is very stout. This condition began after marriage twelve years ago; present age 33. The patient has no children; menstruation irregular as regards both time and quantity. She has a good appetite and is quite energetic; no mental dullness. Thyroid, pituitary extract, ovarian extract, dieting, and iodides have been tried without result. Before marriage the patient was quite slender.

Treatment of Syphilis

Dr. E. TYTLER BURKE (Salford) writes: The case upon which Dr. A. L. Pirrie seeks advice in the *Journal* of January 17th (p. 123), although originally a simple one of sero-positive primary syphilis, must now be regarded as one of endo-syphilis heading towards Wassermann-fastness and permanent grave visceral damage chiefly in the cardio-vascular and central nervous systems. The treatment one would recommend is as follows: bivatol, twice weekly for eight weeks (iodides for last four weeks); stabilarsan, once weekly for eight weeks; bivatol, twice weekly for eight weeks (iodides for last four weeks); stabilarsan, once weekly for eight weeks; bivatol, twice weekly for eight weeks; stabilarsan, once weekly for eight weeks; bivatol, twice weekly for eight weeks. The duration of the treatment is fifty-six weeks, during which, with no rest intervals, there are given 18.6 grams of stabilarsan and sixty-four injections of bivatol of 2 c.cm. each, amounting to 3.84 grams of bismuth metal.

Income Tax

Assessment of Stipend from Appointment

"W. A. R." took up an appointment at £150 per annum as from March, 1929. At the end of June, 1929, he gave up a post and began practice elsewhere. He is now being assessed on the basis that the £150 is separate from his general earnings, and the result appears to be to increase his liability as compared with that calculated on the basis of including all earnings in the general assessment.

*** "W. A. R." appears to have no legal remedy. Fees paid by public authorities are assessed as part of general earnings, but a stipend is legally chargeable under Schedule E separately. But we are not clear that the ultimate result would be different, because if, say, £100 of the stipend is thrown into the general assessment at his present district, the balance would undoubtedly have to be changed in the former district, under the provisions dealing with *ceasing income. In other words, our correspondent* had £150 for the year 1929-30, and on either basis the revenue is entitled to tax thereon.

Obsolescence—Cash Basis

"W. A. W." (1) A car was bought in 1927 for £365 and that amount has been reduced by yearly depreciation allowances to £268. The car was sold in 1930 for £150 and a new car bought for £340. What allowance is due? (2) He proposes to retire from practice in July, 1931. Will he be liable to account for tax on amounts received after that date for previous services?

*** (1) £268—£150=£118 can be claimed as an "obsolescence allowance" in computing the profits of the year 1930. (2) They will not be liable as additional receipts. The only way in which they could affect taxation would be if the authorities insisted on a revision of the period April 5th, 1930, to July, 1931, to an "earnings" instead of a "cash receipts" basis, but that is unlikely in view of the additional charge for obsolescence occurring in the year 1930.

LETTERS, NOTES, ETC.

Medical Congress at Bangkok

The eighth Congress of the Far Eastern Association of Tropical Medicine was held last month at Bangkok, under the presidency of Prince Thavara, physician-in-ordinary to the King of Siam. The following description of the reception given to the delegates who attended this congress is extracted from a private letter sent home by a member of the British Medical Association: "The most prominent feature was the extraordinary and astonishing way in which we were entertained and welcomed by our hosts. Twenty-eight to twenty-nine hours from Bangkok we were met by several Siamese who had been sent down to look after us. At the station our guides had arranged flags along the platform to indicate the hotels to which we had been assigned. Before going to our hotels we were taken to the information bureau and given numbered badges, and two books about Siam, each, I think, specially compiled for the occasion. Fifty cars were available during the week to take us from meetings and entertainments. One morning I visited the waterworks, which are excellent. Bacteriological samples are taken five times daily. We were shown the sampling, which was beautifully done, and also the analysis figures, which are very good indeed. . . . The mosquitos in Bangkok are very numerous, but there is said to be little malaria about." The letter then refers to a performance of the "lantern dance"—a rare event—given in honour of the congress. "The lanterns were carried by seventy-two boys, who expressed in song the hopes of Siam that the health of her people would improve as the result of the congress. . . . In the interval of the 'khow' (mask dance) the delegates were presented to the King and Queen of Siam. All the royal princes are working very actively as heads of the various departments." The writer mentions that about 170 members of the Far Eastern Association of Tropical Medicine were present at the congress, and an even larger number of associate members from Siam. He was particularly struck by the general use of the English language, very well spoken, by all the Siamese officers and by the hotel staffs.

Glycerin as a Surgical Dressing

Dr. H. A. MORTON WHITBY (Hampstead) writes: Dr. Kyle's letter (*Journal*, January 10th, p. 75) and the subsequent correspondence on the subject interest me considerably as I have been in the habit of using glycerin, on account of its hygroscopic and apparent bactericidal action, for burns and accidental and operation septic wounds for several years with very good results. In combination with liq. hyd. perchlor. it acts as an excellent paint for all kinds of cellulitis, and, of course, is well known as a gargle. Two years ago I started to use plain glycerin for the injection of tuberculous abscess cavities, after evacuation of the contents and cauterizing with iodized phenol. I must have treated some thirty cases or more by this method, and in all the wounds healed with a minimum scar.

Dr. H. W. WEBBER (King's Tamerton) writes: As far as I am aware, no one in the recent correspondence has mentioned the combination of ichthyol with glycerin (equal parts). I learnt the use of this from a note in the *Practitioner* some years ago, and have proved its value on many occasions. In cases of lymphangitis it acts remarkably well; septic wounds of the fingers with the accompanying inflamed lymphatic vessels and glands clear up most satisfactorily with one or two applications.

Linseed for Constipation

Dr. W. GLEGG (Menton, France) writes: The use of whole linseed as an effective remedy for deficient bulk in the intestinal contents in constipation might be better known at home. Here it is supplied in tins, imported from Sicily, and it is cleaned from adventitious matter. Two teaspoonfuls, more or less, are taken, washed down with water without chewing. This is repeated daily, morning or night, and combined, when the stools require softening, with small doses of a reliable high-density brand of liquid paraffin.

Painless Natural Labour

Dr. A. BURN (Crawley, Sussex) writes: The case of painless natural labour which I reported three years ago (January 21st, 1928, p. 120) has just been repeated. The same patient had her second child—an eight-pound boy—by the same painless means last week. The labour lasted for two hours—that is to say, uterine contractions and dilatation of the os were only noticed two hours before the child was born. The sole inconvenience of which the patient complained was a dull ache in the groins whenever the uterus contracted. Another point of interest is the fact that the father of the child is suffering from post-lethargic Parkinsonism.

Tuberculin Clinic

Dr. W. CAMAC WILKINSON writes to announce that the work of the Tuberculin Dispensary, hitherto carried on at 82, Fitzroy Street, W.1, will be carried on henceforward at 11, Nottingham Place, W.1. The institution will be called the Tuberculin Clinic, and for the present it will be open on Mondays and Fridays, from 1.30 to 4 p.m.

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48, 49, and 50.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 31.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

91 The Tuberculin Reaction in the First Three Years of Life

S. MONRAD (*Ugeskrift for Laeger*, November 6th, 1930, p. 1046) published in 1914 an account of tuberculin tests performed on about 3,400 children, and concluded that during the first year of life a positive reaction is always associated with active tuberculosis; in the second year it is so in six out of seven cases, and between the ages of 2 and 5 in two out of three cases. Since these investigations were undertaken so long ago as the period 1907–14, the author has thought it worth while investigating whether there has been any change in this respect, and he has therefore made a similar study of cases for the period 1919–30. Of 52 infants under the age of 12 months giving a positive reaction, all showed clinical signs of active tuberculosis. Of 104 children in their second year with a positive reaction, 92 showed clinical signs of active tuberculosis; and of 93 in their third year giving a positive reaction, 76 showed clinical signs of active tuberculosis. The sombreness of the prognosis, when a tuberculin reaction is obtained early in life, is emphasized by the same material. Of the 52 in the first year of life, 42 (80.8 per cent.) died; of the 104 in the second year of life, 37 (35.6 per cent.) died; and of the 93 in the third year of life, 21 (22.6 per cent.) died.

92 Measles Complicated by Diabetes Insipidus

V. ANGELINI (*Clinica Pediatrica*, November, 1930, p. 992) records the case of a girl, aged 5, in whom, after a mild attack of measles, polyuria and polydipsia developed, accompanied by anorexia and loss of flesh. The amount of urine passed in the twenty-four hours ranged from 5,200 to 7,600 c.cm., with an average of 6,100 c.cm. Micturition occurred about nineteen times a day; during the night the frequency of micturition and the quantity of urine passed were about the same. The specific gravity of the urine was 1003 to 1004, and the urinary chloride figure was 4.27 to 7.32 grams, as compared with 8.68 to 13.49 grams in a normal child of the same age and weight. Injection of extract of the posterior lobe of the pituitary gland temporarily reduced diuresis to a minimum of 1,400 c.cm. and a maximum of 1,800 c.cm.; the specific gravity rose to 1010, and the chlorides from 0.7 to 2.8 per 1,000. The ocular fundi were healthy, and radiography of the brain showed a normal sella turcica. The case did not come to necropsy, but Angelini suggests that the condition was due to an organic lesion of the diencephalon and hypophysis by the measles toxin.

93 Diagnosis of Aneurysm of the Heart

B. STRANDELL (*Acta Med. Scand.*, November 15th, 1930, p. 148) recalls the earlier work of Sternberg on the clinical course of cardiac aneurysm, in which the following stages of the disease might be differentiated: attacks of stenocardia; pericarditis and softening of the heart muscle; a stage of latency; and a stage of severe injury to the heart muscle. Despite the recognition of these manifestations, the diagnosis of cardiac aneurysm during life remains very difficult, even with the help of radiography. Strandell records four cases of aneurysm of the heart, in three of which the diagnosis was not made until necropsy, although two of them were radiographed. The Wassermann reaction in all three was negative. The fourth patient was a man, aged 42, who had been infected with syphilis at 26, the Wassermann reaction being positive. In the summer of 1928 the patient began to get attacks of angina, from which he gradually recovered. A year later, after a prolonged anginal seizure, radiography showed a distinct rounded shadow which remained visible at the apex when the patient was rotated. In view of the age and history of the patient a diagnosis of cardiac aneurysm due to syphilitic coronary thrombosis was made. He died eighteen months after the onset of symptoms, and at the necropsy were found two cardiac aneurysms, one involving the apex and the other the posterior wall of the left ventricle. The appearance of the aneurysms suggested the possibility of rupture, since they contained no muscle in their walls, and communicated with the cavity of the ventricle by small openings. The pericardium was very firmly adherent to the aneurysms. There was arterio-sclerosis and narrowing of the lumen in the coronary arteries, but no evidence of syphilitic involvement.

94 Subacute Inguinal Lymphogranulomatosis

A full description is given by P. CHEVALIER and J. BERNARD (*Rev. de Méd.*, December, 1930, p. 856) of a special form of inguinal adenitis, which was first noted by Nicolas, Durand, and Favre, and has been termed by them subacute inguinal lymphogranulomatosis; it is also known as the disease of Nicolas-Favre. The condition is universal, and is far more common in males, especially adults, than in females. The infection is conveyed genitally, and the disease is essentially venereal, with an incubation period of 10 to 25 days. The onset is usually insidious and slowly progressive. The first symptoms are discomfort in the groin with slight malaise; anorexia, fatigue, and arthralgias are generally observed. An inguino-iliac adenitis with marked periadenitis supervenes; as a rule this is unilateral, the ganglia on the opposite side being only slightly hypertrophied. The stage of suppuration which follows may last for months or even years. The process ends in a dense fibrous sclerosis. The disease may be complicated by an extensive suppuration or by a chronic inflammation and fibrosis which obliterates the lymphatics. Recurrences are exceptional. The authors enumerate various clinical forms of the disease, and discuss its pathological anatomy and differential diagnosis. Treatment is essentially medical, but local radiotherapy has given satisfactory results. Internal remedies recommended are iodine (orally or intravenously), and injections of emetine, antimony tartrate, and copper sulphate. Cure has also been obtained by the use of vaccines and tuberculin. Though Nicolas has found internal treatment unsatisfactory, the present authors hold the contrary opinion.

95 Percutaneous Immunization in Diphtheria

H. BAAR and H. BENEDICT (*Klin. Woch.*, December 20th, 1930, p. 2395), acting on the principle that the production of an erythema at the site of application of toxoid facilitates its absorption, made use of a mustard plaster before the toxoid was applied by inunction according to Lowenstein's method of active immunization against diphtheria. They found that of 106 children so treated 85 became negative and 21 remained positive; at the end of six weeks only 4 were still positive. Comparison of these figures with the results obtained by the original method shows a remarkable improvement, especially since all cases were scarlet fever patients, who, as Kundratitz and Hartmann-Karplus have shown, are more difficult to immunize than other children.

96 Curability of Congenital Syphilis

According to E. A. MORGAN (*Canadian Med. Assoc. Journ.*, December, 1930, p. 811) the securing of a permanently negative Wassermann reaction in congenital syphilis depends primarily on the stage of the disease when treatment is commenced. In the early stage 80 per cent. can be cured, in the latent stage 64 per cent., and in the late stage 49 per cent., provided that the treatment is continued for a reasonable time, which he suggests is eleven months for the early stage, and twenty-eight

months for the latent and late stages. Highly resistant cases in infants are found only in about 8 per cent., in the latent stage in 15 per cent., and in the late stage in 34.5 per cent. This estimate is founded on the results obtained in treating 270 cases during the last eleven years. Morgan adds that some cases will become Wassermann-negative even if treatment is incomplete, and he has collected evidence that the time factor is of importance in the production of such a negative reaction.

97 Recovery from Pneumococcal Meningitis

R. BHAGEERUTTY (*Thèse de Paris*, 1930, No. 377), who records nine illustrative cases, including that recently reported by H. Stoessiger (*Epitome*, June 7th, 1930, para. 521) in patients aged from 6 days to 38 years, states that, though pneumococcal meningitis is almost always fatal, recovery may sometimes ensue owing to the following bacteriological and therapeutical factors. There may be an attenuated form in which only a small number of pneumococci are present, and the cerebro-spinal fluid is clear. Serum treatment is occasionally successful. Repeated lumbar puncture may diminish the tension of the cerebro-spinal fluid, and help to expel the micro-organisms and their toxins. The organic resistance of the patient is probably the chief cause of recovery.

Surgery

98 Osteomyelitis Treated by the "Orr" Method

I. E. DEIBERT (*Annals of Surgery*, December, 1930, p. 1087) reviews 100 cases of acute and chronic osteomyelitis and compound fractures treated by the "Orr" method; 37 were acute, 57 chronic, and 6 compound fractures. The age incidence was from 1 to 47 years, and every bone in the body was included in the series with the exception of the skull. It was found that the predominating organisms were the *Staphylococcus aureus* and *albus* with an occasional *Streptococcus haemolyticus*. Orr's operative treatment consists in the making of a fairly large incision over the infected bone area and the spreading apart of the skin, muscles, fasciae, and periosteum to afford sufficient access. A window is chiselled into the diseased area to provide drainage; dead bone is removed, and the infected parts are cleaned gently with a curette. The wound is dried and wiped out with 10 per cent. tincture of iodine and then 95 per cent. alcohol; it is packed wide open with sterile paraffin gauze, and covered with a sterile pad and bandage. A plastic bandage or splint is applied to immobilize the parts and keep them in a correct position. No dressing of the wound is undertaken for several weeks unless there are signs of acute sepsis or because of the odour. The average time for changing the plaster case and dressing was from three to five weeks. In the cases under review there were six deaths from acute osteomyelitis in children for whom treatment had been delayed, but in the remaining cases 75 per cent. of the patients are clinically well. It was found that the wound healed more quickly than by other methods of treatment, the bony defects were fewer, and the subsequent sequestration and secondary operations were lessened. The closed plaster bandage reduced the liability to secondary or mixed infection, and no case of ankylosis of adjacent joints was seen. It was found to be the type of treatment most comfortable for the patient.

99 Diagnosis of Tumours involving the Spinal Cord

From his experience of 300 cases at the Mayo Clinic H. W. WOLTMAN (*Journ. Amer. Med. Assoc.*, November 8th, 1930, p. 1398) states that pain is the first symptom in 80 per cent. of cases of tumours involving the spinal cord. This pain is commonly referred along the segmental distribution of a posterior root; it is frequently of a squeezing or piercing nature, suggesting thoracic or abdominal disease. The segmental distribution of pain is circumferential in the trunk and lengthwise in the limbs. As the tumours grow, the involvement of neighbouring roots affords a guide to the direction of the extension; thus a unilateral sciatica may become bilateral. Pain is increased by any action, such as sneezing, which increases the tension of the cerebro-spinal fluid. Root pains commonly wake a patient between 3 and 4 a.m., and relief is obtained by sitting up or sleeping in a chair, whereby a relative shortening of the spinal cord is effected. The exacerbation caused by flexing the head on the thorax is a valuable diagnostic sign; it is due to traction on the cord. Disturbances of motility and sensibility, and of sphincter control, have a lesser value as localizing signs. High cervical tumours may be associated with sensory disturbances affecting the lower limbs only, and the exposed situation of the decussating pyramidal tracts may lead to a quadriplegia unassociated with such disturbances. Involvement of the descending root of the fifth nerve may cause facial sensory change and, because of the proximity to the foramen magnum, to signs suggesting cranial tumour. Manometric readings of the cerebro-spinal fluid, and their variation when pressure is made on the jugular vein, are much influenced by the obstructive effects of tumours; the fluid itself undergoes changes in colour and chemical composition below the site of the growth. *X* rays are valuable in excluding secondary tumours in bone and primary bone disease, but Woltman has found lipiodol of little service in difficult cases. Among other conditions from which differential diagnosis must be made are multiple sclerosis, retroperitoneal and mediastinal tumours (especially aneurysms), and tabes with associated root pains.

100 Tuberculosis of the Urinary Tract

B. A. THOMAS (*Amer. Journ. Surg.*, November, 1930, p. 308) states that urinary tuberculosis is most often primary in the kidney, is most common in the third, fourth, and fifth decades of life, and occurs about four times as often in males as in females. The right kidney was affected three times as frequently as the left in cases of unilateral disease, the infection almost always arising as a haematogenous infection. Diagnosis must depend not only on the clinical symptoms, but upon bacteriological examination in conjunction with radiography and cystoscopy. It is of the greatest importance that a correct diagnosis should be made before the opposite kidney has become infected. Ureteral catheterization is to be avoided, since this may cause the infection of the other kidney. Treatment of urinary tuberculosis must be both operative and palliative. Early nephrectomy with partial ureterectomy or aseptic nephro-ureterectomy is the procedure of choice in cases of unilateral renal tuberculosis. Spinal anaesthesia, nitrous oxide gas, and ethylene have proved the most satisfactory forms of anaesthesia. In certain operable cases of bilateral involvement, preliminary antituberculous treatment is necessary, and also as a post-operative procedure after nephrectomy. The operative mortality is slight, and a complete cure occurs in about 60 per cent. of cases.

101 Gastric Evacuation

According to Goetze, emptying of the stomach is not brought about by peristalsis, but by a general contraction (systole) of the whole organ, aided by the hydrostatic pressure of the fluid therein, the action being similar to that of emptying the urinary bladder; the cardia closes, the pyloric sphincter relaxes, and the muscular wall contracts. The gastric musculature also has the power of contracting round its contents (peristole) so that, no matter how full or empty, there is always sufficient tone to exert a fairly constant pressure on the contained fluid. In order to confirm this theory in the human stomach, K. H. SCHMIDT (*Deut. Zeit. f. Chir.*, November, 1930, p. 192) has estimated the pressure in different parts of the stomach by passing one thick-walled rubber tube into the antrum, and another into the fundus at the same time, after partly filling the stomach with a thin barium mixture. The level of the fluid in the tubes represents the pressure in that part of the stomach, and is demonstrated by *x* rays. By connecting the upper ends of the tubes to Marey's tambours, and thence to a kymograph,

variations in pressure can be recorded. Schmidt finds that the normal intragastric pressure is from 2 to 25 cm. of water, and consists of the hydrostatic pressure together with the pressure due to the tone of the muscle wall. Differences of pressure in different parts of the stomach are due solely to the level of the tubes in the fluid—that is, to hydrostatic pressure—the active pressure due to the stomach wall being the same all over the organ. A general increase of pressure precedes emptying of the contents through the pylorus. Peristaltic waves usually follow this increase of pressure, but do not themselves increase the pressure in the stomach. After expulsion of the contents the pressure falls again to normal, even though vigorous peristalsis may continue. The fundus probably plays a more important part in this emptying mechanism than the antrum. The erroneous view that peristalsis caused expulsion of the stomach contents has been held because the systolic contraction of the stomach is not demonstrable by *x* rays. Actually, peristalsis in the stomach has a purely mixing and triturating action.

102 Artificial Pneumothorax in Pneumonia in Infancy

During the prolonged course of a case of pneumonia in an infant aged 10 months an interlobar effusion was suspected. On exploration some blood-stained serous fluid was removed, but a pneumothorax was accidentally produced. In spite of this, no increase of dyspnoea or other untoward symptom ensued; the temperature actually fell to normal almost at once, and the child made an uninterrupted recovery, although before the pneumothorax the course of the illness had been long and the prognosis had been unfavourable. This observation led J. DUKEN (*Klin. Woch.*, November 22nd, 1930, p. 2195) to treat seven other cases by producing an artificial pneumothorax on the affected side. In most of these there was similar improvement, though it was found that several refills might be necessary before the temperature returned to normal. In no case was there any untoward symptom which could be ascribed to the introduction of the air. Duken points out that in pneumonia the affected part of the lung, being less active, occupies a smaller space than the normal. In the adult the other lobes undergo a compensatory emphysema, but in the child, owing to the relatively rich interstitial tissue, this compensation is not so complete. The mediastinum tends to be drawn towards the affected side, and the pneumonic lung takes more than its share of blood supply. Both these facts can be demonstrated radiologically. The induction of artificial pneumothorax, by diverting more of the blood to the healthy side (in consequence of the pressure alterations), will actually improve cyanosis in children suffering from severe unilateral pneumonia, and the author has used it for this purpose with considerable success. The cases have been very carefully selected, the indications being: (1) protracted course of pneumonia without response to conservative therapy, (2) marked cyanosis, and (3) anticipation of the development of bronchiectasis. Pneumothorax should not be induced if there is pneumonia or bronchitis in the other lung. J. JAHR and R. NEUMANN (ibid., p. 2200) have used the same treatment in five cases and record similar results.

103 Idiopathic Dilatation of the Oesophagus

F. A. C. SCRIMGER (*Arch. of Surg.*, Part II, December, 1930, p. 1315) describes idiopathic dilatation of the oesophagus, cardiospasm, or achalasia cardia as being second only to cancer in frequency of diseases of the oesophagus. Idiopathic dilatation occurs most often in the thoracic portion, and signifies a diffuse enlargement of the lumen of the oesophagus; the abdominal portion below the diaphragm is not dilated, but is usually thickened and contracted. The oesophagus is also elongated, and may measure up to 46 cm.; it may contain from 1,500 to 2,000 c.cm. of fluid. The wall becomes thickened, and the mucosa frequently inflamed, friable, or ulcerated. It is suggested that the disease is secondary to degenerative changes in the vagi, the closure of the cardia being due to the normal tone acting without nerve control. The condition usually develops before the age of 40; the onset may be sudden and progression intermittent, the chief symptom being difficulty in swallowing and the regurgitation of large quantities of frothy food mixed with saliva. Two cases are reported in which extramucosal oesophagoplasty was performed; in one of these the patient made a good recovery, with satisfactory results a year after operation; in the other case the patient died from a mediastinal infection. In a third case, operation consisted in the exposure of the cardiac end of the stomach through a Marwedel incision, the cutting of the coronary ligament of the liver, and the turning downward and to the right of the left lobe of the liver, thus exposing the cardiac end of the stomach and the subdiaphragmatic portion of the oesophagus. An incision was then made forward through the crura of the diaphragm, the dilated portion of the oesophagus being brought through the opening for at least an inch. This operative procedure avoided the danger of tearing the oesophagus; a risky suture is obviated. In the case so treated recovery was smooth, and soft food could be swallowed after the usual lapse of time.

Therapeutics

104 Antimony in Therapeutics

Though antimony has fallen more or less into disuse in medicine, C. N. MYERS and B. THRONE (*Journ. Lab. and Clin. Med.*, December, 1930, p. 239) show from a history of the drug that it has been a most valuable remedy in the treatment of disease. Particular study has been made of a preparation (M 303) which is composed of both arsenic and antimony; in it one molecule of nitro-hydroxy-phenyl-arsenic acid is reduced with one of nitro-hydroxy-phenyl-stibinic acid, the resulting compound containing the two salts, each in the trivalent condition. This compound, known as the base, is insoluble in ordinary solvents; treated with hydrochloride acid, a soluble preparation is obtained when the hydrochloride solution is precipitated from ether. In this product the favourable ratio between the toxic and the therapeutic dose renders it more satisfactory than any drug now available. Administered intravenously, its action in the treatment of syphilis and leprosy has indicated markedly its value in diseases due to protozoal infections.

105 Fruit Treatment of Diarrhoea in Children

The good results obtained in cases of coeliac disease treated with fruit diet induced FANCONI (*Deut. med. Woch.*, November 14th, 1930, p. 1949) to try the effects of a similar diet in the acute, subacute, and chronic diarrhoeas of children over 1 year old. In the earlier cases the improvement, though marked, was only temporary, the return to ordinary diet being followed by a recurrence of diarrhoeic stools. This was, however, subsequently avoided by the addition of whole milk, cereals, and sugar to the fruit diet very gradually during convalescence. For the first day or two after admission to hospital the children with acute enteritis were given raw fruit only, either fruit juice (orange or bilberry) or mashed bananas; grated apple was sometimes used in conjunction with or instead of the banana. The appetite, general condition, and stools of the children improved rapidly. Unsweetened buttermilk or almond milk (prepared by mixing an almond meal with warm water) was then added to the diet, the next step being the administration of small quantities of potato purée and sieved steamed vegetables. Milk curd or protein almond milk was included towards the end of the first week, and sour whole milk was gradually substituted for the buttermilk during the second week; crusts and rusks or other cereal foods were also gradually introduced again in small amounts about this time. In the milder cases the diet in which fruit preponderated was continued for a fortnight; in the more severe and the recurrent forms of colitis the fruit and vegetable diet, with the addition of liver, meat, egg-yolk, and milk products, has been continued for months, and in coeliac disease even for years, with beneficial results. The

stools may remain bulky during the treatment because of the large proportion of cellulose in the diet; this, however, does not retard recovery. The temporary loss of weight which occurs during the first few days is due to the low salt content of the diet.

106 Sodium Amytal in Neuro-psychiatric Conditions

W. J. BLECKWENN (*Journ. Amer. Med. Assoc.*, October 18th, 1930, p. 1168) defines narcosis as deep sleep or unconsciousness, more or less prolonged, and rapidly induced by drugs—a condition similar to surgical anaesthesia but not so profound. He has found its induction a most valuable procedure in many neuro-psychiatric states, such as various types of excitement and benign depression, katatonia of the stuporous, cataleptic, and negativistic forms, and in various convulsive conditions (status epilepticus, eclampsia, and tetany). Periodically induced narcosis in these cases simplifies their management and materially shortens the illness; to obtain this effect sodium amytal administration is advocated. Since deep anaesthesia is not desired, the technique differs from that used in surgical anaesthesia. The patient should have no food for four to six hours preceding the administration. The drug is freshly dissolved in water which has been distilled three times, and a 5 per cent. solution is made, each cubic centimetre thus containing 0.75 grain of the drug. The solution is injected intravenously at a rate not exceeding 1 c.cm. per minute. The initial dosage varies with different cases; for neuro-psychiatric patients it is said to be quite safe to give 2 c.cm. more than is necessary to produce corneal anaesthesia. The average patient will thus receive between 7 and 15 grains, or approximately half the amount used for surgical anaesthesia. If given intramuscularly the dose is increased, and the solution is more concentrated. From 2 to 5 c.cm. (10 to 20 grains) of a 20 per cent. solution is given. This narcosis is slower and less profound than that induced by the intravenous method. In mild cases the drug can be given orally in 3 to 6 grain doses; it takes 45 minutes to act by this method, and is effective as a hypnotic in the less severe types, but is useless in disturbed or violent cases. The patient must always be watched from the time of the administration of the drug until the initial narcosis has worn off, because of the danger of aspiration of vomited matter and the possibilities of suffocation. During more than a year Bleckwenn has given over 2,000 injections in 184 cases. He is impressed by the fact that the drug can be used daily over long periods without any untoward reactions. If the method described is followed, the reactions of greatly lowered blood pressure and shallow respirations are avoided. Sodium amytal, it is added, should be used with caution in cases of advanced arterio-sclerosis.

107 Injection Treatment of Paget's Disease

P. DELMAS-MARSALET (*Journ. Méd. de Bordeaux*, November 30th, 1930, p. 900) records the case of a man, aged 60, who on March 27th reported increase in the size of the head, bowing of the lower limbs, loss of teeth, dyspnoea on exertion, violent headaches, muscular cramps, and blanching of the fingers which had lasted for years. With the usual bony changes of Paget's disease there was a prolonged systolic bruit, and the arteries were markedly sclerosed. Radiological examination showed typical thickening and a flocculation of the cranial wall, and the sella turcica was irregularly enlarged; the femora were broadened and bowed, the medullary canal was enlarged, and the femoral arteries were calcified. For three months 50 drops were given daily of a solution of irradiated ergosterol and 60 intragluteal injections of calcium gluconate. Irrasterine was then combined with the calcium preparation and also calcium chloride. The treatment represented a total of 78 grams of calcium gluconate, 33 grams of calcium chloride, and 0.63 gram of irradiated ergosterol. During treatment the cranium did not increase in size, and the headaches, cramps, and blanching of the fingers nearly disappeared, but the blood pressure was unaltered. Radiological examination in June showed evidence of cranial recalcification; the inner table was reconstituted throughout practically its entire extent, though the outer table was still flocculent in appearance. In September the inner table was found to be entirely reconstituted, while the outer table could be delimited throughout its whole extent. Calcification of the falx cerebri in the subethmoidal region was now apparent, and this was considered an indication for the cessation of treatment. Recalcification similar to that in the cranium was noted in the femora, but there was no increase of calcification of the femoral arteries. The author observes that the pathological anatomy of Paget's disease shows a double process of resorption and new formation of bone; he inclines, however, to the view that decalcification is the fundamental change.

Laryngology and Otology

108 Treatment of Vasomotor Rhinitis by Sclerosing Fluid

RICHIER (*Arch. Internat. de Laryngol., Otol.-Rhinol., et Broncho-Œsoph.*, July–August, 1930, p. 843) reports a method of treatment which he has used in 150 cases of vasomotor rhinitis. The cases for this method must be those of purely congestive rhinitis, and not of the parenchymatous or polypoid variety. The nose must be carefully prepared by antiseptic lotions for one week. The mucous membrane is then completely retracted by cocaine and adrenaline solution, retained for ten minutes, and followed by a further application of adrenaline. Richier employs a 5 per cent. solution of the double hydrochloride of quinine and urea. The injection is made by three punctures into the internal surface of the inferior turbinate, and two punctures into the inferior surface. It is essential that the injection should enter deep into the erectile tissue, since otherwise sloughing may result. Richier as a rule requires 5 c.cm. of solution to inject both turbinates. The patients usually complain of a little pain in the nose and face following this treatment, and occasionally temporary deafness (quinine) is observed. A spray of adrenaline and cocaine is ordered daily for one week, after which no further treatment is needed. The author claims that this method is vastly superior to the classical treatment by the galvano-cautery, which requires many applications and is inconstant in its action, and, furthermore, often results in the formation of troublesome adhesions between the turbinates and septum.

109 Treatment of Infected Tonsils by Diathermy

DAUDIN-CLAVAUD (*Rev. de Laryngol., d'Otol. et de Rhinol.*, October, 1930, p. 605) commends diathermy for the treatment of small and medium-sized infected tonsils, and in those patients who object to removal, but who have tonsils which exude pus or caseous material on pressure. He describes two main tonsillar crypts, a superior and an inferior, both of which spring from one superficial sinus. All other crypts are small and secondary, and lead out of these two major crypts. Bipolar diathermy is used, one electrode being placed in the crypt, and the other moved over the surface of the tonsil. In this way all the tonsillar tissue between the surface of the tonsil and the depth of the crypts is destroyed; when healing is complete, the crypts have ceased to exist, and the retention of pus or infected material is rendered impossible. The tonsils and faucial pillars having been painted with Bonain's solution, the cotton-covered right-angled applicators are moistened with the solution, and are introduced into the two major crypts. Entirely satisfactory anaesthesia can be obtained in this way, and peritonsillar injection of anaesthetic solution is unnecessary. An electrode in the form of a right-angled blunt hook is then inserted to the bottom of the inferior major crypt, and coagulation is effected by a movable electrode; this is placed first at the most posterior part of the tonsil, conducted round the inferior portion, and brought finally to a point immediately over the stationary electrode. The blunt hook is then moved to the superior major crypt, and the superior portion of the tonsil is coagulated similarly. One session is usually sufficient. There is

often some pain after the operation, but always less than after complete tonsillectomy. The author has had some cases of secondary haemorrhage on the fifth day, but these caused no anxiety.

110 Primary Carcinoma of the Trachea

F. A. FIGI (*Arch. of Otolaryngol.*, October, 1930, p. 446) reviews the incidence of primary carcinoma of the trachea at the Mayo Clinic since 1918. Although 470 cases of laryngeal cancer were seen, there were only five tracheal cases. These five patients ranged in age from 29 to 77 years; three were women. Carcinoma secondarily invading the trachea is a much more frequent lesion. The symptoms may develop insidiously, or may appear abruptly following an acute infection of the upper air passages. There are paroxysms of coughing, and dyspnoea which at first is only present on exertion but later becomes extreme, being generally both expiratory and inspiratory. Small clots of blood may be coughed up, but acute haemorrhage is usually of late occurrence. Hoarseness is most commonly a late symptom, and is due to the involvement of the recurrent laryngeal nerve. There is as a rule very little loss of weight. The clinical course is rapid, the duration being a few weeks to a few months. Death is due to respiratory obstruction, pneumonia, or haemorrhage. Metastases develop late or not at all. Histological examination of the tumours recorded in the literature demonstrates glandular carcinoma as the most common type of growth. Squamous-celled carcinoma was found, however, in three of the five cases at the Mayo Clinic. The diagnosis is made by indirect laryngoscopy or by bronchoscopic examination of the trachea, and the author points out that all cases of dyspnoea, when physical and *x*-ray examinations of the thorax are negative, should be subjected to bronchoscopy. The prognosis is unfavourable in the upper portion and practically hopeless in the lower part of the trachea. The treatment suggested is tracheofissure and removal of the growth by surgical diathermy, followed by intensive radium treatment of the lymphatic area.

Obstetrics and Gynaecology

111 Heart Disease in Pregnancy

Discussing pregnancy in the cardiac patient, W. D. REID (*Journ. Amer. Med. Assoc.*, November 15th, 1930, p. 1468) points out that the diagnosis of heart disease in patients under the age of 40 is rarely justifiable without one or more reliable signs; in the elderly the reverse is true. Most pregnant women are younger than 40. The first essential in these is an accurate diagnosis of the cardiac condition, since organic cardiac disease is found to be absent in many pregnant women who have suspicious symptoms. Cardiac disease, if present, is nearly always a rheumatic manifestation. The average age at death of this class of patients is 35.5 years. Statistics show that the average age of death was 42.4 years for married women with heart disease, and 47.2 years for unmarried women. The average number of children of married women in the group which was analysed was 5.75. The mortality from cardiac disease in pregnancy is but slightly greater than that of other cardiac patients of similar age. Probably 90 per cent. or more of cardiac patients survive pregnancy and parturition. Reid concludes that married women with rheumatic heart disease die before their time because of the natural evolution of this disease rather than of child-bearing. This, he adds, should be considered when advising cardiac patients regarding marriage and pregnancy. G. HERMANN and E. L. KING (ibid., p. 1472) emphasize the importance of repeated electrocardiographic studies in pregnant women the subjects of heart disease, and records 24 cases, which are grouped in the order of their severity and various complications. The serious significance of bundle branch block, and the hopeful possibility of its temporary, transient nature, are demonstrated. Auriculo-ventricular block, fibrillation, and the less serious abnormalities and their effect in the cardiac function are also discussed. The state of the heart muscle is of the utmost significance. Alleviation of congestive heart failure before permitting labour or surgical delivery to proceed is necessary for success. Ether was found to predispose to fatal pulmonary oedema in patients with the lung congestion of mitral stenosis. Of the general anaesthetics ethylene is the first choice as regards the cardiac condition, but local anaesthesia is much the safest. Acute rheumatic endocarditis occurring during pregnancy responded to treatment, and subsided as in non-pregnant cases. Extensive and usually fatal pulmonary thrombosis is shown to occur relatively frequently in instances of serious idiopathic myocardial degenerative changes.

112 The Anterior Lobe of the Pituitary and the Ovary

E. PHILIPP (*Zentralbl. f. Gynäk.*, December 6th, 1930, p. 3076) endeavours to correlate the histological structure of the anterior lobe of the hypophysis at various ages, during pregnancy and after castration, with its hormonal activity on the ovary as shown by implantation experiments in immature female mice. The prehypophysis of non-gravid mature human females gives a well-marked prolan reaction (Zondek and Aschheim) of Grades I, II, and III; it is specially rich in chromophilic cells. After castration the prehypophysis contains increased numbers of eosinophil cells, and its implantation produces a specially well-marked prolan A effect (Grade I reaction). Implantation of the foetal prehypophysis, or that of the newborn infant, the mostly undifferentiated cells of which contain a few eosinophils, gives occasionally a slight Grade I reaction. The prehypophysis of older children, which contains more numerous chromophils, causes a well-marked Grade I reaction. In these, as in castrated subjects, prolan A is demonstrable in the urine. According to Philipp's view the pregnancy reaction of Zondek and Aschheim is due to the presence in the urine of a hormone not derived from the prehypophysis but from the chorion. He thinks that the only instance of the "pregnancy reaction" of the urine being due to a prehypophyseal hormone is that of women after castration.

113 Surgical Treatment of Placenta Praevia

TURENNE (*Gynécol. et Obstét.*, October, 1930, p. 289) summarizes the advantages of Caesarean section in the treatment of placenta praevia. The technique is familiar and within the power of those possessing general surgical experience; the operation is very speedy and gives good visual access. It follows that the foetal as well as the maternal risk is lessened, and that quick and complete delivery of the placenta is assured. Treatment by arterial ligature or by hysterectomy is easily undertaken if uterine inertia complicates the section. Tears of the cervix and lower uterine segment, which frequently contribute to a fatal termination, are avoided. The disadvantage of Caesarean section is the risk of infection; this is greatly diminished by early operation. In appropriate cases a low Caesarean or Portes's operation should be performed. The following are among the conclusions which have been unanimously adopted in Uruguay. Cases of placenta praevia should be sent to hospital as soon as they are diagnosed. Delivery through the vagina should be restricted to cases in which the placenta is comparatively remote from the internal os, and to cases well advanced in labour in which cervical, placental, or foetal injury is improbable. Caesarean section is indicated (1) whenever, with little or no cervical dilatation, the placenta can be felt, even if little or no bleeding is present; (2) in cases with well-dilated cervix, with the placenta in the area of the internal os, and with considerable actual or recent haemorrhage or any degree of persistent haemorrhage; and (3) when after persistent or repeated haemorrhage clinical examination reveals thickening of the lower uterine segment and malaccommodation of the presenting part. When an abdominal intervention is planned no vaginal examination or manœuvre should be made. With few exceptions, and in every case in which infection is suspected or certain, a Mikulicz drain should be used at the end of the operation.

114 Therapeutic Use of the Reflex Action of the Round Ligament

F. IMIANITOFF (*La Gynécol.*, November, 1930, p. 652) gives an account of the therapeutic employment of the reflex action of the round ligament. He has found that a course of stimulation of this reflex is of great value in the treatment of retroversions, chronic metritis, subinvolutions, tubo-ovarian congestion, and inflammation of the gland of Douglas. The particular reflex present in the round ligament is of sympathetic origin, and is provoked by stimulation of the periphery of the pubic hairs, or the internal aspect of the thighs. A high-frequency current is considered the most appropriate stimulus. The reflex acts by producing a contraction of the smooth muscle fibres of the round ligament. Since these are in direct continuity with the fibres of the uterine wall, a slow and generalized contraction is instigated, causing erection of the uterus and pulling it forwards. The repeated stimulation of the ligamentary reflex has a tonic effect on the genital apparatus, resulting in the re-education of the uterine band. This stimulation is accompanied by hyperaemia of the pelvic basin. Contra-indications are acute and subacute inflammations, adhesions, large tumours, malignant tumours, and the latter half of pregnancy. The author records results of 135 cases treated in this manner. He cured thus 42 out of 60 cases of retroversion; 24 of 32 cases of congestive dysmenorrhoea; 10 of 14 subinvolutions; while of 17 cases of tubo-ovarian congestion, 3 were cured, 10 alleviated, and 4 were unrelieved.

Pathology

115 Enumeration of Blood Platelets

I. OLEF (*Arch. Int. Med.*, October, 1930, p. 585) describes an improved method for the enumeration of blood platelets; he finds that the most satisfactory preserving fluid is a solution containing 2 grams of sodium metaphosphate and 0.9 gram of sodium chloride in 100 c.cm. of distilled water. It is essential to avoid all contact between the undiluted blood and any surface to which platelets tend to adhere, and pipettes and counting chamber are discarded. A drop of blood freshly drawn from the skin after washing with soap and water and alcohol and ether, pressure being avoided, is allowed to fall into a small paraffin cup containing some of the diluting fluid, to form about 1 in 10 dilution; this is stirred with a wooden applicator coated with paraffin, and a few drops of the mixture are transferred to a cleaned glass slide, covered with a cover-slip, and sealed. The platelets and red cells are counted in random fields taken in different parts of the specimen until 250 to 500 cells (in each of two preparations) have been seen. A red cell count is then made in the usual manner, and the absolute number of platelets per cubic centimetre is determined. The results obtained are higher than those of previous similar methods, the maximum in Olef's series being 1,108,000 per c.mm. and the minimum 407,000; the average for males was 650,000, and for females 587,000. It was noted that when the platelet count is below 500,000 per c.mm. the platelets tend to be large.

116 Renal Innervation

A. M. DOGLIOTTI and M. MAIRANO (*Arch. Ital. di Chir.*, September, 1930, p. 109) discuss the innervation of the kidney and the effects of section of the nerves and decapsulation. They describe the anatomy and functions of the renal nerves, and found by experimental investigations on dogs that partial interruption of the nerves going to the kidney is sufficient to relieve pain. As regards the vasomotor function of these nerves, they found both vaso-constrictor and vaso-dilator fibres present, the latter in small numbers. After section, regeneration was completed in the nerves, tested anatomically and functionally, in four to six months. The results of complete resection and of simple sympathectomy of the periarterial branches are also discussed. The effects of decapsulation were studied in 23 cases; the capsule was rapidly replaced, and was already evident after six to eight days. The new capsule was less elastic and the normal transcapsular anastomosis was destroyed, but a few days later vessels which could be injected were present, and for a short period afterwards there was an increase in the circulation in the kidney. Functionally, an improvement was observed similar to that seen after periarterial sympathectomy. An extensive bibliography is appended.

117 Increase in Virulence of the B.C.G. Strain

P. UHLENHUTH and W. SEIFFERT (*Zeit. f. Immunitäts.*, December 23rd, 1930, p. 187) conducted virulence tests on two strains of tubercle bacilli that had been isolated in 1902. One of these, Tb.18, was of bovine, the other, Tb.1, of human origin. In repeated tests on rabbits and guinea-pigs during the years 1926-30 these two cultures proved to be relatively avirulent, showing, if anything, a slight progressive fall with advancing time. In spite, however, of their relative avirulence to the majority of animals, occasional guinea-pigs inoculated developed severe generalized tuberculosis. Passage experiments, using material from these animals, proved negative, and the authors concluded that these exceptional results were due to a peculiarly high susceptibility of the individual animals, and not to an increase in the virulence of the organisms. In one experiment, however, an apparent rise in virulence to guinea-pigs did occur. Four rabbits were inoculated with Tb.18, and though scarcely any lesions resulted, the organs of these animals set up fairly severe tuberculosis in a number of guinea-pigs inoculated with them. From this the authors conclude that a bovine strain which partially regains its virulence may behave not unlike a human strain, being virulent for guinea-pigs but not for rabbits. Of even greater interest were experiments made with the B.C.G. strain. Seven guinea-pigs were inoculated intraperitoneally with 5 mg. of culture. After 14 months one of these animals died of severe generalized tuberculosis. Cultures were prepared from the organs, and 1/10 to 1/100 mg. were inoculated into ten fresh guinea-pigs; all these animals died in seven to ten weeks from severe generalized tuberculosis. Similarly, three rabbits inoculated with culture or with tissue died in three months with severe generalized tuberculosis. It is suggested, therefore, that under certain conditions the B.C.G. strain may revert to the fully virulent condition.

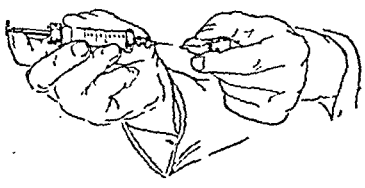
118 Anaerobic Blood Culture by the Boëz Method

By means of the anaerobic blood culture by the Boëz method Dr. M. STOLZOVÁ-SUTORISOVÁ (*Bratislavské Lekárske Listy*, November, 1930, p. 594) states that he has been able to recover pathogenic microbes in 27 out of 29 cases of sepsis. As a control the cultivation of the organisms in the same cases by means of the usual broth-glucose method succeeded in only 10 cases. The Boëz method, which was originally described in the *C. R. Soc. de Biologie*, 1924, allows the simultaneous cultivation of both aerobic and anaerobic forms. At the same time the bactericidal properties of the blood are destroyed by the addition of acid citrate (which lowers the *p*H) to the venous blood. Another advantage is the possibility of transporting the blood to a distant laboratory without destroying the microbes.

119 Local Vascular Changes in Splenic Anaemia

J. MCMICHAEL (*Edin. Med. Journ.*, January, 1931, p. 1) defines three distinct groups of local vascular changes in splenic anaemia—namely, hyaline changes, splenic phlebitis, and the appearance of the siderotic nodule. The first is said to be common after the age of 10, and is associated with lymphoid involution changes; it has no pathological significance. Splenic endophlebitis is probably determined by raised portal blood pressure, the calcification and thrombosis being secondary phenomena. The siderotic nodules result from periarterial haemorrhages due to the congestion of the spleen rupturing the ellipsoidal capillaries. In cases of hepato-lienal fibrosis there was found a constant relation between these nodules and haematemesis, and the author attributes both to the increased portal blood pressure.

Calcium is not absorbed in the absence of vitamin D



Fundamental relationship between calcium metabolism and vitamin D is to-day an established fact. The availability of "Ostelin" vitamin D in a colloidal solution makes it possible to combine the hypodermic administration of calcium and vitamin D

Indications

All vasomotor disturbances of the capillary vasomotor system, such as *chilblains, chilblain circulation,* urticaria and angio-neurotic œdema; also in delayed union of fractures, and in the severe nutritional failure encountered in tuberculosis and other debilitating diseases.

"Colloidal Calcium with Ostelin" vitamin D is also useful in the treatment of the patchy areas of congestion and breaking down of the skin in the lower leg from varicose veins. It may be used with benefit in the palliation of varicose ulcers, and it appears to have a definitely beneficial effect in promoting better capillary circulation and healing.

Administration

By injection subcutaneously. One injection every 3, 5, or 7 days. When the condition to be treated is severe or urgent, one injection daily for several days.

COLLOIDAL CALCIUM *with* OSTELIN VITAMIN D

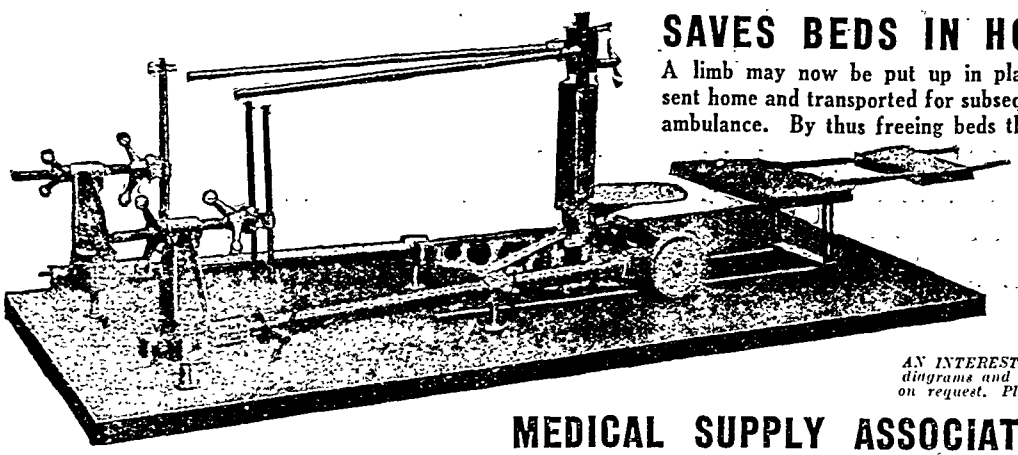
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

Saltair Surgical Service

SALT'S PATENT GASTROPTOSIS BELT

SURGICAL SERVICE SALTAIR

Fig. A shows slightly dilated and much dropped stomach radiographed in the upright position immediately after partaking of a barium (6 oz.) "Umbrose" meal. The greater curvature projects 3½" below a line drawn between the iliac crests.

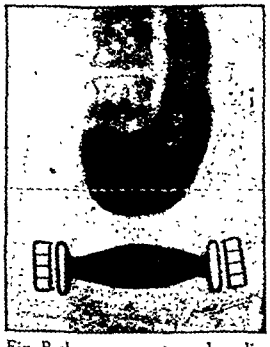

Fig. B shows same stomach radiographed 15 mins. later, the patient having lain upon a couch, the bottom feet of which were raised 9". The Belt was then applied, the patient allowed to walk about 5 or 6 minutes, and the radiograph taken in upright position.

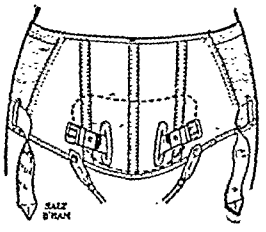
This Belt was designed by us in co-operation with a well-known X-ray specialist.

The construction is such that the upper part allows of free expansion of the abdomen, whilst the lower part and pads are fixed. The support consists of a metal plate padded with spongy rubber and having transverse springs. On pressure being applied by the springs, the pad sinks into the soft abdominal tissues, so that, on the patient rising, it is impossible for the stomach to drop below the upper margin of the pad.

Every Gastroptosis Belt (or Corset) is made specially for the individual case to the Medical Adviser's prescription, and can be supplied in grades and qualities to meet the needs of all.



Front View.

Fig. A.
Front View of Springs and Pad.

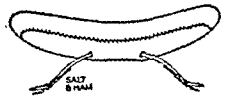


Fig. B.
View from top showing thickness of spongy rubber pad and position of steel springs.

Guarantee

"We guarantee to alter, exchange, or accept the return of any Appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported, on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS

arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

(MIST. HEPATICA CONC. HEWLETT.)

Composition.—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.
This preparation does NOT come under the Dangerous Drugs Act.

THIS excellent compound has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz.; 10-oz.; 22-oz.; 40-oz; and 90-oz. Bottles. Price in England, 12/6 per pound.
This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable *condition*.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge.
Every facility for specialised investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental *Departments and the Bio-Chemical, Pathological, and Psychological Laboratories*.
Furthermore provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

L. O. NEED, Town Clerk.

County Borough of West Ham.

APPOINTMENT OF JUNIOR ASSISTANT MEDICAL OFFICER (MATERNITY AND CHILD WELFARE).

Applications are invited from fully qualified unmarried Women Medical Practitioners for the post of JUNIOR ASSISTANT MEDICAL OFFICER in the Medical Officer of Health's Department.

The duties will mainly consist of work in connection with the Council's Maternity and Child Welfare Scheme. The person appointed will be required to devote her whole time to the service of the Council and to work under the direction of the Medical Officer of Health.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700.

Applicants should have had previous experience in Maternity and Child Welfare work and possess a Diploma in Public Health.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of that Act. The statutory contributions (5 per cent.) to the Superannuation Fund under the Act will be deducted from the salary.

The appointment will automatically terminate on marriage.

Application forms may be obtained from the Medical Officer of Health, Town Hall, West Ham, E.15, on receipt of a stamped addressed foolscap envelope, and must be returned to the undersigned not later than February 7th.

CHARLES E. CRANFIELD, Town Clerk.

Town Hall, West Ham, E.15. January 20th, 1931.

County Council of Middlesex.

DISPENSER.

The County Council invite applications for the post of Dispenser at HILLINGDON HOSPITAL, Uxbridge, Middlesex, at a salary of £250 per annum (no bonus).

Candidates must be Graduates in Pharmacy of a recognized University or hold one of the qualifications of the Pharmaceutical Society of Great Britain. The officer appointed must be acquainted with the running of the pharmaceutical department of a modern hospital, and ability to undertake simple biochemical and microscopical investigations will be additional qualifications.

The officer appointed will be required to devote whole time to the duties of the post, to contribute to the County Council's Superannuation Fund, and for the latter purpose will be required to pass such medical examination as the County Council may direct.

The appointment is terminable by one month's notice on either side.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than February 7th.

No special application forms are provided. Envelopes must be endorsed "Dispenser."

Canvassing, directly or indirectly, will be a disqualification.

Guildhall, Westminster, S.W.1. January 14th, 1931.

ERNEST S. W. HART, Clerk of the County Council.

City of Stoke-on-Trent.

ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the appointment of Second Assistant Resident Medical Officer at the LONDON ROAD INSTITUTION, near Newcastle, Staffs.

The remuneration assigned to such office is £200 per annum, with board and residence. The period of the appointment will be limited to one year, subject to termination by one month's notice on either side. The Institution accommodates about 1,000 inmates, including 600 in Hospital (which is recognized as a major training school for nurses) and 150 in Mental Wards. The medical service to the adjacent Children's Homes is performed by the Institution Resident Staff, who, also, are required to lecture to Nurses.

Applications, accompanied by copies of not more than three testimonials of recent date, should be delivered to the undersigned not later than first post on Friday, February 13th next. Applicants should state particulars of qualifications or degrees held, the date thereof, when taken, and experience since qualifying. Preference will be given to those who have had experience in any of the following subjects—viz., Anaesthetics, Obstetrics, Pathology, and Radiography.

E. B. SHARPLEY, Town Clerk.

Who is your Patient?

A MAN or woman? Adult or child? A very necessary question when you prescribe a remedy for constipation—unless it is Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein. Then you need to give thought only to the dose. And that is simple. Begin with a tablespoonful for adults and a teaspoonful for children, at bedtime. Reduce the dose as improvement takes place.

No excess of mineral oil to make adjustments of the dose necessary. An emulsion as fine as it can be made, that mixes thoroughly with the intestinal contents, carries unabsorbable moisture to them and makes evacuation easy and painless.

Besides, it *gently stimulates* peristalsis, and thereby makes the result certain and the re-education of the bowel function possible.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

HORMOTONE
BRAND

in disorders of the

CATAMENIA

and the

MENOPAUSE

Hormotone supplies the physiological stimulus to the endocrine glands, whose functional activity determines the normal catamenial flow.

When these internal secretions begin to fail at the period of the menopause, Hormotone acts both by substitution and homostimulation.

Dose: One or two tablets three times daily.

PARKE, DAVIS & CO.

ADRENALIN

The Product of Unique Experience

PARKE, DAVIS & Co. introduced Adrenalin to the medical profession in 1901.

During the thirty years that have elapsed, they have manufactured it continuously, and their long experience has convinced them that natural Adrenalin possesses many advantages over the synthetic product.

Adrenalin (P., D. & Co.)—the original and well-tried preparation—is extracted from the medullary portion of selected adrenal glands. The isolated substance is then standardised by both physiological and chemical methods to secure full activity of the finished preparations.

Medical men can make sure of obtaining an Adrenalin that is potent, uniform in action, and reliable by specifying "P., D. & Co.".

Full particulars of Adrenalin (P., D. & Co.) and its uses in medicine will be supplied on request. Adrenalin Chloride Solution, P., D. & Co., is supplied in bottles and ampoules. Hypodermic Tablets, Inhalant, Lozenges, [illegible] etc., and Adrephine (Adrenalin Compound) are also available.

PARKE, DAVIS & CO., BEAK STREET, LONDON, W.1.

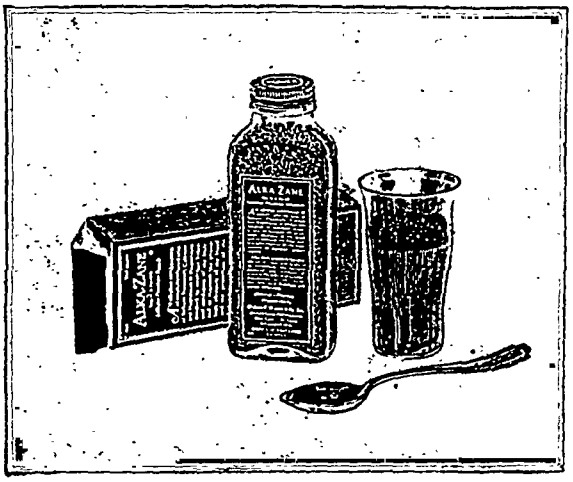
D

In Hyperchlorhydria



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

and other conditions of gastric over-acidity, Alka-Zane will afford prompt relief from distressing symptoms and restore normal alkaline balance.

Diuretic and antacid, Alka-Zane is indicated wherever the alkali reserves are unduly depleted, as in intestinal disturbances, rheumatic affections and certain anaphylactic manifestations.

ALKA-ZANE

Literature and samples to physicians on request.

LEWIS'S PUBLICATIONS

READY NEXT WEEK. *ENTIRELY RE-WRITTEN.*

With 49 Coloured Illustrations on 20 Plates, and 123 Figures in the Text.
Pp. xvi + 562. Demy 8vo, **35s.** net, postage 1s.

DISEASES OF THE TONGUE

By W. G. SPENCER, M.S., F.R.C.S., Consulting Surgeon, Westminster Hospital, and STANFORD CADE, F.R.C.S., Assistant Surgeon, Westminster Hospital; Surgeon, Mt. Vernon Hospital.

Being the Third Edition of Butlin's "Diseases of the Tongue."

After careful consideration, the Authors decided that, although the progress made in the forty-five years since Butlin's book first appeared necessitated its entire re-writing, they felt that no better foundation for a book on Diseases of the Tongue could be found than the work of Henry Butlin. They have endeavoured, therefore, to preserve the identity, while introducing the new work on the various subjects which have been brought into relation with diseases of the tongue.

Stoddart's MIND AND ITS DISORDERS.
By W. H. B. STODDART, M.D. Fifth Edition. With 11 Plates (6 Coloured) and 76 other Illustrations. Demy 8vo. 21s. net, postage 9d.

NATURAL APERIENT MINERAL WATER
OF
RUBINAT LLORACH
(Hydragogue, Purgative, and Cholagogue.)

The official analysis shows in each litre about 1601.321 grains of **Anhydrous Salts**, of which are **Sulp. Soda** 1485.368 grains, and **Sulp. Magnesia** 50.301 grains.

Prescribed in cases of Gall-stones, Liver Disease, and threatened Appendicitis, Constipation associated with Gout, Hepatic Dyspepsia, Gastric Fever, and generally in Abdominal Obstruction.

DOSE.
Wineglassful fasting; can be increased according to temperament. Effect is more rapid if followed by a cup of hot tea.
NO GASTRIC IRRITATION. NO ALTERATION IN DIET REQUIRED.

"A moderately powerful stimulant of the liver, and a powerful stimulant of the intestine.

Greater Comfort for your Patients.
"The Rose Corset-Belt"
which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.
Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.
I have also invented an improved Colotomy Belt for both male and female patients.
My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.
MADAME ROSE, 97, Mortimer St., Regent St., W.1. LANGHAM 1575.

FOR DEAFNESS
Doctors use and recommend Ardente
because it fulfils its claims.

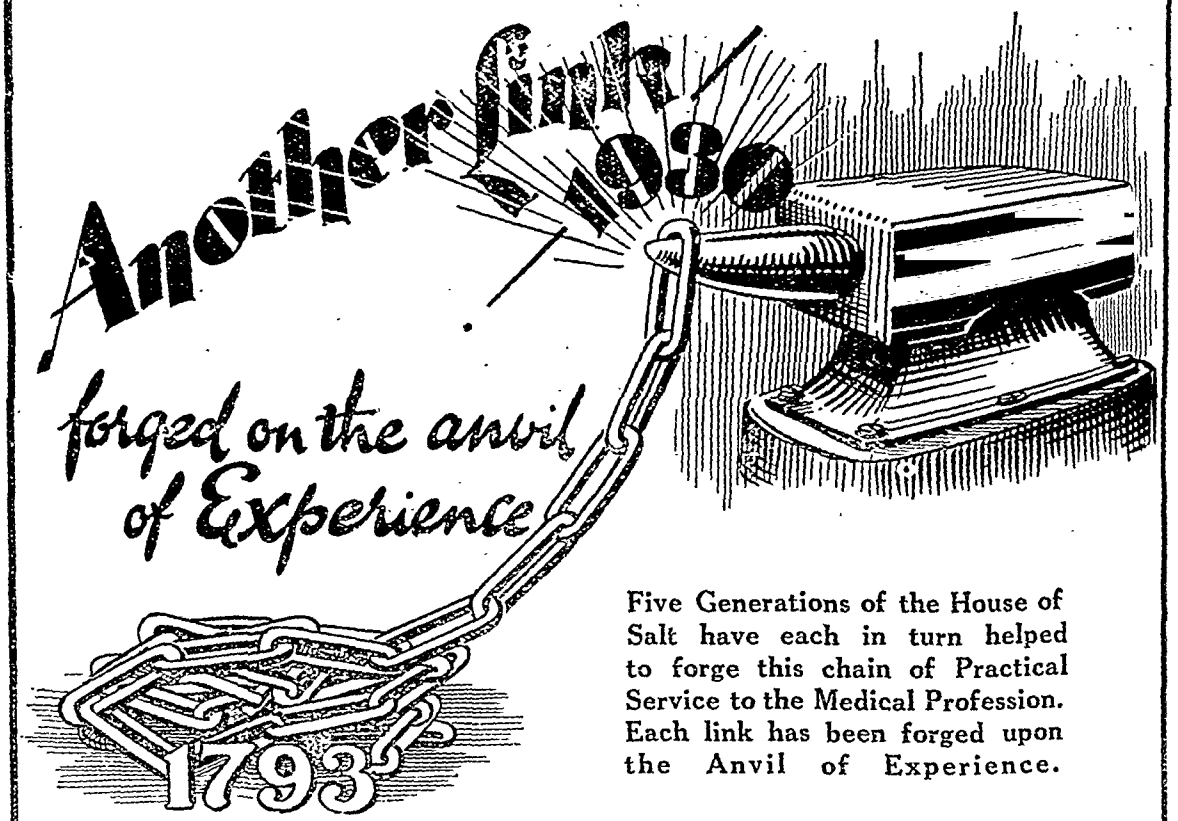
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, *if not found suitable* within fourteen days from date of supply."

Salt and Son Ltd.



Five Generations of the House of Salt have each in turn helped to forge this chain of Practical Service to the Medical Profession. Each link has been forged upon the Anvil of Experience.

It is thanks to their unswerving endeavours that "Salt's" to-day enjoy the reputation, throughout the Medical Profession, of being in the foremost rank as Manufacturers of Surgical Appliances, and of being the most reliable source of supply.

Our Guarantee itself stands surety for the High Standard of all our Products, which are made individually for each patient with the strictest attention to the smallest detail in the prescription of the attendant practitioner.

Comfortable Post-Operative Support for Your Surgical Patient.

Danger of nephroptosis following the removal of a large abdominal tumour probably indicates careful support for your patient.

Ruptured appendix with drainage places such a heavy tax upon the vitality of your patient that you may wish to recommend the wearing of an abdominal support during convalescence.

Or a sensitive scar after a gall-bladder operation may need the protection of a special support, with laparotomy pad.

After any abdominal operation, a Spencer supporting corset or abdominal belt gives your patient great comfort and sense of security. The support can be made of light as well as of firm material. It can be soft and pliable for comfort. But because each Spencer support is especially designed for the person who will wear it, it will give the support that you want your patient to have.

This is a Supporting Corset with the front opened to show the inner belt which supports the abdomen. Adjustment of the belt is made from the outside of the support.

The Spencer Corsetière will call at your surgery or at your patient's home to take the necessary measurements, and to get your special instructions about the case in hand. Spencer corsets and supports are never sold in shops.

If there is no Corsetière in your vicinity write direct to us.

We issue booklets on the use of Spencer Supports for the relief of sacro-iliac strain, hernia, enteroptosis, movable kidney, and for maternity and post-partum wear. We will gladly send you any of them in which you are interested.

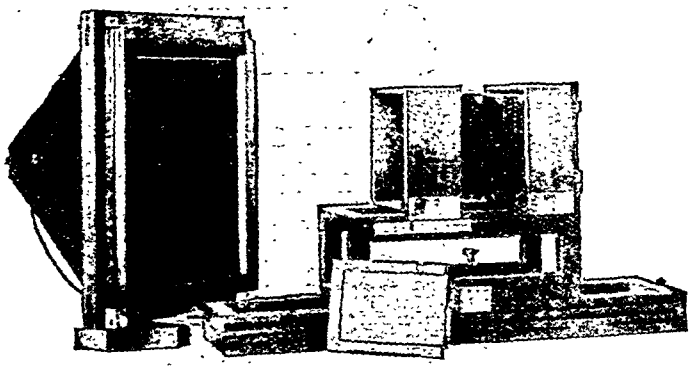
"Kodak" X-Ray Reduction Camera



A simple and solidly built camera. Reduces negatives of any size up to 17 x 14 ins.

Suitable for making bromide prints or transparencies of $6\frac{1}{2}$ x $4\frac{3}{4}$ size or smaller, and lantern slides.

An automatic focussing scale makes the "Kodak" Reduction Camera exceedingly simple to operate.

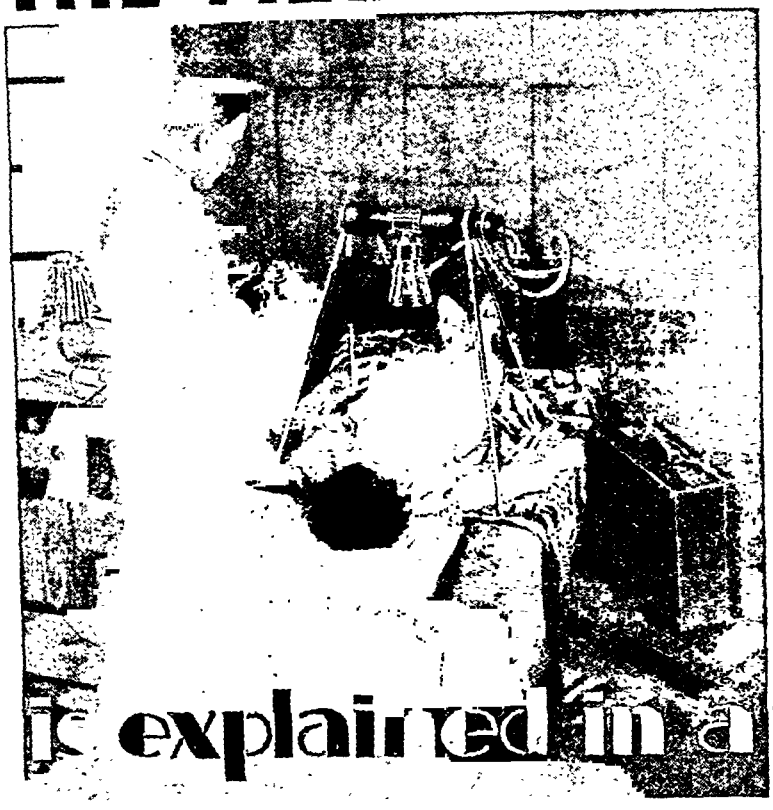
THE 'METALIX-PORTABLE



explained in a few words

The illustration shows the "Metalix-Portable" being used in a patient's home to make a radiogram of the pelvis—on a full size (12" x 15") film. The outfit is connected to an electric light socket, the back of the time-switch consulted to obtain the correct exposure time, the button depressed, and an excellent picture assured.

Should the patient touch any part of the outfit during the exposure no harm could possibly result, whilst the doctor is equally well protected against both high tension and unwanted radiation.

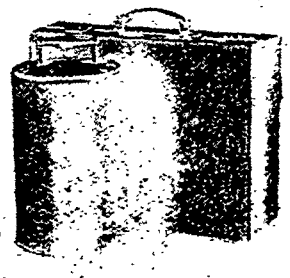
With equal facility and safety, visual screen examinations can be made, the screen image often being sufficient for the purpose of diagnosis.

The "Metalix-Portable" is no longer new; for over two years a steadily increasing number of general practitioners have become "Metalix-Portable" users and enthusiasts. It is now a recognised item of equipment of the progressive medical man.

A publication containing full facts about the "Metalix-Portable," with specimen radiograms and convincing medical testimony, will be sent on request.

Price of complete "Metalix-Portable" outfit for operation on standard A.C. voltages, £138 . 0 . 0. For D.C. voltages, £25 . 0 . 0 extra.

Packed as shown here, the "Metalix-Portable" is carried with the utmost ease.



PHILIPS METALIX-PORTABLE

PHILIPS LAMPS LTD. (X-Ray Dept.), PHILIPS HOUSE, 145, CHARING CROSS ROAD, LONDON, W.C.2.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

Salvitae

A formula that demonstrates its scientific value.

Manufactured by American Apothecaries Co, New York.

In Infancy

WHETHER the child be breast-fed or bottle-fed, constipation is often a troublesome feature. Castor oil and other purgatives, or aperients, while securing a prompt action of the bowels, possess certain definite disadvantages with which the practitioner is fully acquainted.

"Cristolax," a combination of 50% of the purest medicinal paraffin of correct viscosity and 50% "Wander" Dry Malt Extract, is of special value for infants, particularly for those who are artificially fed.

One teaspoonful dissolved in three feeds a day, no matter whether they consist of milk or infants' food, renders the feeds more easily digestible, prevents the formation of hard indigestible clots, and keeps the bowels in a regular and sweet condition.

"Cristolax" is also an admirable preparation for the nursing mother, both during gestation and the lying-in period. Its use ensures regular and adequate defecation without griping, straining, or harmful effect upon the child.

MALNUTRITION and MARASMUS

Mellin's Food when given in conjunction with cow's milk and water produces an immediate gain in weight in fermentative dyspepsia and in wasting disorders of early infancy. For the prematurely born infant Mellin's Food proves invaluable.

As is well known, sugars exhibit varying tendencies to fermentation in the digestive organs. Milk sugar ferments most rapidly, less rapidly cane sugar, and maltose still more slowly, and the high percentage of dextro-maltose in Mellin's Food accounts for its usefulness in all such cases of malnutrition.

Mellin's Food

The booklet "Modified Milk in Infant Feeding" deals fully with the use of Mellin's Food in cases of malnutrition, and will be gladly sent together with samples to Members of the Medical Profession.

MELLIN'S FOOD LTD., LONDON, S.E.15.

Symptomatic relief in 5 minutes

THE symptoms of common cold—congestion, discharge and obstructed breathing—are frequently distressing. From the patient's point of view, they constitute the essence of the annoyance from which he is seeking immediate relief.

Rapidity of action is characteristic of Mistol. Consisting of menthol, camphor, eucalyptol, and chlorbutol in a light oily solution that spreads promptly to all parts of the nasal mucosa, it relieves congestion, reduces discharge and clears the nasal passages within five minutes.

This symptomatic improvement also benefits the pathological state and tends to shorten the duration of the cold. Venous stasis in the mucous membrane is corrected, hyperemia diminished, and over-activity of the secreting glands checked. Repeated instillations of Mistol promote a more rapid return to normal conditions within the nares.

The formula of Mistol is the result of long and careful research, suggested primarily by prescriptions used for many years by leading rhinologists.

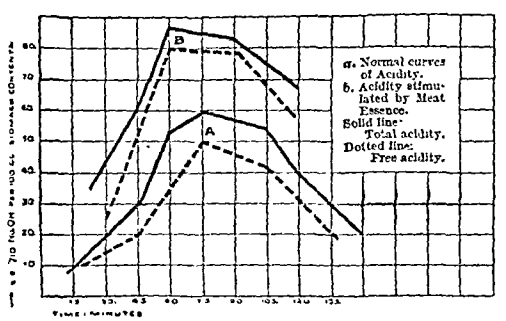
Conserves the patient's energy— no strain on the digestive system when these essences are taken



Graph showing acidity found when meat essences are taken

BRAND'S
ESSENCES OF BEEF
OR CHICKEN

When the appetite needs stimulus, and the body needs to be invigorated without demands on the digestive system, Brand's Essences of Beef or Chicken have been found to be indispensable. Recent scientific tests have shown that these essences are assimilated by the digestive organs forty minutes quicker than ordinary foods and without the formation of any residue.

In convalescence and in all cases of intestinal disturbances, whether the lesion is catarrh or cancer; in states of exhaustion when the patient's recovery is hampered by anorexia; in specific fevers and in all disorders associated with pyrexia; in the post-influenzal state and before and after operations, these Essences supply energy and prepare the system to accept and digest a more solid diet.

Hygienically prepared by an *exclusive* process from the finest freshly-killed English meats, Brand's Essences of Beef or Chicken are suave and non-irritant in action. For these reasons 99 doctors out of every 100 recently interviewed, recommend them. Samples will be gladly sent on receipt of a professional card. Brand & Co. Ltd., Dept. F 22, Mayfair Works, South Lambeth Road, London, S.W.8.

Proverbs Up-to-date No 2

PREVENTION IS BETTER THAN CURE

An excellent maxim — and one that holds good for such conditions as *are* curable. Unfortunately Dental Caries is not, so that *Prevention* is the only satisfactory method of combating this affection.

In this connection, it must be remembered that the Dentist is a surgeon, who is called upon, more often than not, to remove diseased and useless tissues; which are replaced by appropriate artificial substitutes. It is in the mission of preservation and prevention that Gibbs co-operate with the Dentist.

"Visit your Dentist twice a year, and use Gibbs Dentifrice twice a day" is a phrase reiterated in Gibbs nation-wide advertising. The vital function of the Dentist in the plan of preventive dentistry is never left in doubt; and the twice daily use of Gibbs Dentifrice is urged as the best way to consolidate his good work. Gibbs Dentifrice has for many years won the approval of leading Medical Authorities. It provides a cleansing agent which removes all harmful deposits — quickly and surely — whilst bringing out the natural beauty of the teeth by safe polishing.

GIBBS DENTOZONE

A Peroxide Mouth Wash in Powder form. A new Preparation by Gibbs that has met with instant success. Gibbs Dentozone produces Oxygen in the mouth, which has a wonderfully efficient cleansing and antiseptic effect; and definitely purifies the breath. Although intended for twice daily household use, Gibbs Dentozone provides an excellent and safe mouth wash for use following extractions.

Gibbs Dentifrice

BRITISH MADE

Literature, propaganda material, kinematograph films, leaflets, etc., as well as samples, are always freely at your disposal. Address: Dental Dept. 2 W X, D. & W. Gibbs Ltd., London, E.1.

Monsol Ointment

Monsol Throat Pastilles.

Monsol Dental Cream.

Monsol Medicated Soap.

Monsol Pessaries.

The efficiency of a germicide depends on the ratio of its germicidal power to its destructive or irritant action on living tissue. The higher this ratio the greater the effective concentration in which it can be employed—hence the greater its efficiency.

It has been demonstrated by many years' clinical and research work that this ratio is higher for Monsol than for any known germicide of its class.

This fact, in conjunction with its selective action on the bacteria that cause sepsis, explains its universal use in gynaecology and general medical practice throughout the world.

MONSOL IS *THE SAFE* GERMICIDE.

Alternative Methods in Prophylaxis and Treatment of

CORYZA

DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients.

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat). For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

"The Greatest Contribution to the Cause of Health Education ever made by a Commercial Firm"

—*Medical Opinion.*

"THERE are so many publications which one is advised to have as a desk book that to apply that term to any work is almost sufficient to blast its career. In 'What to Do if it's Catching,' however, that remarkable compilation issued by Newton, Chambers & Co., Ltd., of 'IZAL' fame, we, as medical officers of health, have indeed a desk book of the most helpful nature in the control of infectious disease.

When one appreciates the great difficulty of giving explicit rules regarding the isolation of cases treated at home, the easiness with which some point is forgotten, either in giving the instructions or carrying them out, 'What to Do if it's Catching' is to the medical officer, and the family involved, a veritable chart in their sea of trouble. This is only one example of the merits with which this book is filled.

In my opinion this is the greatest contribution to the cause of health education ever made by a commercial firm."

———, M.D., D.Sc., Ch.B., D.P.H.,
Medical Officer of Health,
County Borough.

FREE

A special complimentary copy will be sent free to Doctors on request. Please address to Newton, Chambers & Co., Ltd., Dept. M12, Thorncliffe, Sheffield.

"What to Do if it's Catching" has been compiled and published in co-operation with eminent Medical and Health Authorities by Newton, Chambers & Co., Ltd., proprietors of Izal, the disinfectant most used by Public Health Authorities throughout the world. It is a compendium of information written in simple language giving the public directions for preventing the spread of infectious illness in the house and in the district.

IZAL is the disinfectant most used by Public Health Authorities throughout the world.

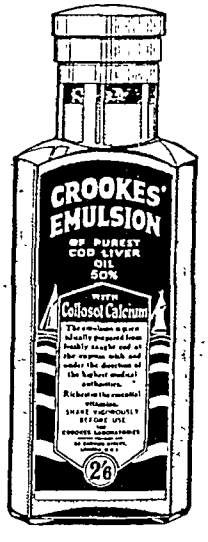
A new Collosol Product

CROOKES'
EMULSION WITH COLLOSOL CALCIUM

Special attention is called to this valuable addition to the range of Collosols.

The emulsion itself contains 50% cod liver oil, from livers of cod freshly caught in British waters, and expressed actually on board the trawler, so that otherwise harmful putrefactive processes do not impair the vitamin content.

This vitamin value is verified by laboratory assay, which gives 19/20 blue Lovibond units, or nearly twice as high as that of ordinary cod liver oil.



The combination of Crookes Emulsion with Collosol Calcium is the outcome of the general acceptance that vitamin D affects absorption, deposition and excretion of calcium. Such indications as Rickets are due to an alteration in the absorption of the latter element, and it is obvious that the effects of vitamin D present in Crookes Emulsion will be greatly enhanced by the readily absorbable form of Collosol Calcium.

As thyroid secretions control iodine metabolism, and insulin controls glucose metabolism, so is vitamin D control responsible for the fate of calcium in the body.

Sample supplies obtainable on application will enable practitioners to confirm, from a clinical standpoint, the great value of Crookes Emulsion with Collosol Calcium.

Issued in bottles, 6 ozs. 2/6, 12 ozs. 4/-

Gratifying results attend its use

Benger's Food—the adjustable diet.

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing. The process may be arrested at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes).

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

"Azoule" Solution A.B.A. TRADE MARK

IN PRURITUS ANI

Accumulating experience confirms the remarkable effect of the new local anæsthetic **'Azoule' Solution A.B.A. in Pruritus Ani and Anal Fissure** (see B.M.J., Aug. 30, 1930). Outstanding features of this product are its prolonged local anæsthetic effect which lasts as long as ten days and its non-toxicity.

Wherever prolonged local anæsthesia is required 'Azoule' Solution A.B.A. is the agent of choice.

Other references: B.M.J., June 15, 1929, p. 1070. B.M.J., June 28, 1930.

'Azoule' Solution A.B.A. is supplied in 2 c.c. ampoules. Boxes of 6 and 12 at 5/6 and 10/-

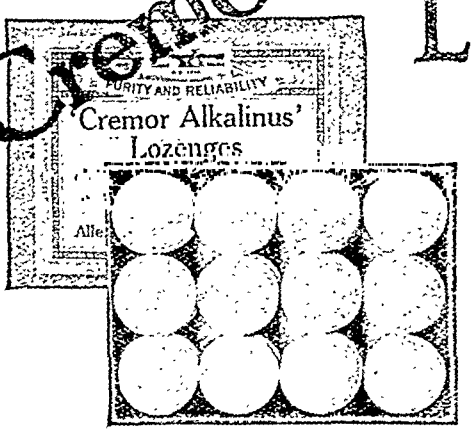
Descriptive literature on request.

Allen & Hanburys Ltd., London, E. 2.

Telephone: Bishopsgate 3201 (10 lines). Telegrams: "Greenburys Edo London."

Cremor Alkalinus

LOZENGES



Trial sample will be sent to all members of the medical profession on application.

Made from **Cremor Alkalinus "A. & H."** Formula C

Sod. Bicarb.	3 parts
Mag. Carb.	8 „
Calcium Carb.	12 „

Each lozenge contains 15 grains.

Two lozenges equal the normal dose.

In flat boxes of 36 lozenges (for the pocket)

In glass stoppered bottles containing 2 lbs., or about 600 lozenges.

Allen & Hanburys Ltd., London, E. 2

Telephone: Bishopsgate 3201 (10 lines). Telegrams "Greenburys Edo London."

Hughlings Jackson Lecture

ON

QUANTITATIVE MANAGEMENT OF CONTRACTION FOR "LOWEST-LEVEL" CO-ORDINATION

BY

SIR CHARLES SHERRINGTON, O.M., M.D., F.R.S.
WAYNFLETE PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF OXFORD

[After some prefatory remarks in reference to the commemorative occasion, the lecturer proceeded]

There, at that lowest level, and at its simplest, is the old-fashioned if time-honoured entity, the motor centre. I hesitate to invite recontemplation of it, it is such oft-worn ground, but in light of some fresh detail it seems to accrete endowment. With it, an initial problem and nowhere more essential, is quantitative adjustment.

MOTOR-UNITS

Sampled by afferent stimulation, the motor centre soon reveals that every reflex fractionates its muscle. The fractionation is not pushed so far as separate muscle-fibres. Soleus has 30,000 muscle-fibres, and the long extensor of the digits 55,000[1]; but nervous co-ordination, as Hughlings Jackson has said, is "based on the anterior horn cell." That cell by its motor nerve-fibre innervates a whole packet of muscle-fibres, 150 and more. This packet of muscle-fibres together with its motor nerve-fibre constitutes what has been for short called a "motor-unit." It is with these units that reflex fractionation deals. It gives numbers not unmanageable—soleus (cat) consists of 230, extensor longus of 330, medial gastrocnemius 500.[2] Such motor-units yield a contraction-wave of 2.5 g., and even of 8 g. A coarse unit, it would seem, to grade with. The more since its contraction runs on the "all or nothing" plan, so that to grade the strength of the stimulus of the contraction-wave is not a means of grading the strength of the contraction-wave itself. The contraction-wave is in so far a fixed quantity independent of the strength of its stimulus. In reflex action, however, we know that the single contraction-wave as an isolated event scarcely happens. What happens, of course, is the overlapping succession of the contraction-waves to form tetanus. This tetanus, when once the mechanical fusion of the component waves is complete, yields in its turn a tension value fixed, in so far that no increase of strength or rate of stimulus will change it further. Such fixity of value for the tetanized motor-unit allows reflexes which can ensure it, to be tested for their share of a given muscle.[3] In this way it is found that in the limb no afferent nerve possesses the whole of any one muscle, and that every afferent nerve has some reflex share in practically every muscle.

The motor-units which make up tibialis anticus (cat) number some 360, and its spinal motor-horn cells are in effect the expanded receptive central ends of these motor-units. Some of the motor-units are larger than others, and to these attach doubtless the larger motor-horn cells. The overlap of central terminals on these large cells, if their density on the cell surface is as elsewhere, must be specially extensive, so that the large motor-units will be the more widely at call and the more often in play. Of the 360 motor-units thus making tibialis anticus the internal saphenous nerve under faradization can tetanize some 110, the popliteal 290, a dorsal digital 125, and so on. That most at least of the motor-units are fully tetanized is shown by the fact that when submitted to additional excitation they show no additional contraction. Motor-units and their motoneurones thus fully tetanized are classed as "maximally" excited, or, in brief, "maximals." We may suppose the central terminals of these afferent nerves to play directly upon the motoneurones, since in the case of this relatively simple reflex, present work discounts the invariable mediation of an internuncial neurone between afferent root and ventral horn cell.

When we find in an experiment that full tetanic stimulation, say, of a plantar nerve tetanizes 180 of the 360 motor-units and stops at that, may we suppose that the anatomical limit of the number of motoneurones reachable by the afferent has been attained? Hardly, for the number thus found may, within limits, fluctuate quite rapidly within the course of an experiment.[4] A slight subconvulsive dose of strychnine will enlarge it, perhaps 25 per cent. Conversely, with spinal shock it shrinks; and so on.

The temporary upper limit represents, therefore, not the anatomical total which the nerve can reach, but some, often large, proportion of that total, a proportion circumscribed by functional condition. And there is abundant evidence that besides those motoneurones which the afferent nerve thus excites, there are others, a subliminal fringe,[3 5] which it acts on but fails to bring to discharge. The proof of this is that an excitation similarly subliminal from another source when brought to bear concurrently on this subliminal fringe does bring it to discharge. We see that part of the explanation of the variation in the number of motor-units a given afferent nerve at different times will excite may lie in subliminal excitation from some other reflex or central source being in action or not on some of the motoneurones at the time.

At the opposite extreme from the subliminal fringe there obtains what we may perhaps term "supramaximal" excitement, a subclass of maximal. By combining tetanizing excitations, say, via two different afferent nerves, the excitement of some motoneurones can be brought to "supramaximal" in the sense of more than sufficient for full tetanic contraction of the muscle-fibres of their units. This is detectable by "occlusion" of contraction[4]; and it commonly happens under faradic stimulation of even a single afferent nerve because of central overlap between its constituent fibres.

GRADES OF EXCITEMENT IN THE MOTOR CENTRE

Therefore among the reflexly excited units of the motoneurone pool there obtain, and often at the same time, three different grades of excitement—*subliminal, maximal,* and, if we distinguish it from maximal, *supramaximal.* What then of the gap between maximal and subliminal? Three years ago Adrian and Bronk[6] on the one hand, and on the other Denny-Brown,[7] by different methods and independently, succeeded in observing reflex firing in the individual motor-unit. They found rates ranging down to 6 per second and 7.5 per second in slow extensor muscles, and down to 15 per second in the motor phrenic. Now these rates are not sufficient to secure in the muscle-fibres a complete tetanus; they are not of maximal grade, in the sense we use that term. They are *subtetanic* in the sense of being incompetent for full tetanus. Different rates, faster and slower, of subtetanic grade were observed to occur concurrently among motor-units firing at the same time in the same muscle.[7] The rates did not correspond with the rate of the break-shock series applied to the afferent nerve.[7 8] These examples were taken from crossed reflexes; there exists there, of course, the circumstance that an internuncial neurone mediates between the afferent nerve-fibre and the ventral horn cell. In the simple flexion reflex the central connexion is more direct, and there the rate of firing of the motor-unit shows much closer correspondence with that of the repetitive stimulus, at least in some of the motor-units and if the repetitive

stimulus be not too quick and strong. But the motor-unit here is prone to fire more than once in response to a single centripetal volley[9] delivered by a single stimulus. This repetitive after-discharge is still greater in some crossed reflexes, and may reach extraordinary proportions. The point is that the firing of the motor-unit does not necessarily agree closely in all cases with impulse volleys entering from the afferent nerve.

Turning from artificial stimulation to natural, we know now, thanks to the discoveries of Adrian and his collaborators, that natural stimulation—for instance, pressure on the foot[10]—will, no less than does the artificial faradic stimulus, develop its reflex by means of impulse-showers, but these are far more diversely arranged. The trains of centripetal impulses engendered by such "natural" stimulations are not only of different rates among themselves, but vary in regularity, and differ in different fibres with heights of frequency related to intensity of the stimulation at different sense organs, and with different periods of crescendo and of adaptation and fatigue. It will resemble a noise rather than a musical note. This complex stream, pouring upon internuncial neurones or directly upon the motoneurone pool, proceeds, however, from a truly functionally related set of receptors. As compared with the centripetal stream sent in by the faradic stimulus to the bared nerve, the natural will have impulses less synchronized and in more dissimilar individual trains. It will exert consequently richer inequality of excitation on the motoneurone pool. In general correspondence with this—though, since the firing of the individual motor-unit may not closely agree with that of the afferent fibre, particular correspondence there need not be—there will result considerable diversity in the firing of the motor-units, and the more so that grade of excitement of the motoneurone governs rate of firing of the motor-unit. The rate of firing of the muscle-fibre can be taken as a guide to the rate of excitation of the motoneurone. The quicker the firing the greater the rate of excitation. Thus, in the phrenic nerve the individual motor-fibre fires more rapidly the stronger the inspiratory action[6]; in the extensor motor-unit firing steadily, weak inhibition[7] by an inhibitory afferent slacks the firing until withdrawal of the inhibition, when the former quicker rate returns.

Clearly in reflex actions, and especially in the more natural and less simple of them, a whole gamut of excitements will obtain in the motoneurone pool. Besides the "maximal" (including "supramaximal") and "subliminal" classes of motoneurone excitement earlier referred to as obtaining together in the reflexly excited motoneurone pool, there will alongside of them be intermediate grades which, since they produce imperfect tetani—*subtetani*—in their muscle-fibres, may be termed *subtetanic*. Where in the motoneurone pool the grade of excitement is greatest is where the successive arrival of converging impulses is quickest and thickest.

ADJUSTMENT OF EXCITEMENT

If we reduce the stimulation of the afferent nerve fewer fibres in it are excited; the field and density of the exciting central terminals are reduced. Supposing we picture the reflexly excited motoneurone pool of a muscle and imagine such a withdrawal of excitation so as to reduce existing excitements by a given, say the just subliminal, amount. We may sample this withdrawal for its effect motor-unit by motor-unit along the scale of excitation of the chart. One consequence is that the total excited field somewhat shrinks. The old subliminal fringe drops out of action altogether, to be replaced by another, in this case not less plentiful, recruited from "subtetanics." All along the firing line firing somewhat slackens. Units well up in the "maximal" class continue to give the same contraction-tension as before; other "maximals" lower down degrade into the subtetanic class, and yield less tension. In the subtetanic class all slip lower, yielding individually less tension, and some cease to discharge, entering the subliminal fringe. In records where two motor-units are firing, one somewhat faster than the other, it can be seen that if the faster slacken somewhat its slower companion may disappear altogether—that is, cease firing. On weak reflex excitation causing the remaining one to quicken again, its companion which had stopped reappears, starting firing again. The waxing and waning affect the two in the same direction, and what will slow one will stop the other. Sometimes, however, one will persist unaltered while another stops.

The total result is a decrease of contraction, which is traceable to several factors. A question rises. Do the motor-units composing a single muscle undergo adjustment concurrently in opposite directions? Are some accelerated while others are slackened? Under certain conditions, rather artificial, this can be observed. Such combination is perhaps more likely with "higher-level" co-ordinations, such as Dr. Blake Pritchard has been investigating, than with the "lowest-level" adjustments I am concerned with now. Though even here there can occur quite fractional inhibitions.

As regards weak reflexes, since a central excitation field reduced to its minimum is entirely subliminal,[11] [12] clearly in weak reflexes the subliminal fringe will constitute a larger proportion of the excited field; and this has been often observed.

As regards strong reflexes, in them excitement of the "maximal" class embraces in certain exceptional examples the motor-units of a whole muscle.[4] Often in strong reflexes "maximal" motor-units are plentiful enough to include all of the motor-units engaged by a weaker reflex; this latter's contraction-tension can then be entirely concealed by the former's.

We have to distinguish, therefore, in our type motor-centre of a muscle certain broad classes in the grades of excitement of the motor-units. Grouping together what was termed above the supramaximal with the maximal so as to make one class—namely, maximal—we have then the three broad classes: subliminal, subtetanic, and maximal. Of these each contributes to active adjustment of the reflex contraction, and each somewhat in its own way.

SUBLIMINALS, SUBTETANICS, AND MAXIMALS

The subliminal fringe group adjusts mainly on the basis of extensity, increasing or diminishing the total number of motoneurones. It, so to say, mediates between excitation and the quiescent pool outside. It also feeds the supraliminal field. Its relation to this latter is sometimes illustrated under conditions strikingly simple. Thus, to take a particular case,[13] two similar volleys are fired into a flexion centre in quick succession. The first excites a reflex twitch in 70 motor-units. The second, following quickly, finds those 70 motoneurones refractory because they have just fired. But in 45 other motoneurones which the first volley excited, though not to the extent of firing them, the second volley finds still some subliminal excitement left by the first, and, itself subliminal for them, yet adds an increment of excitement sufficient for their firing. The myograph gauges their number from their contraction. The exciting volleys are then strengthened, so as each singly to fire 180 motor-units instead of 70. But these two stronger volleys in sequence discover little fringe. Therefore evidently the 45 subliminals of the weaker reflex must have become some of the 180 supraliminals of the stronger. In such an experiment, the summation being confined to two stimuli, opportunity for revealing the whole fringe is small. Temporal summation by its mere iteration possesses powers less limited than spatial summation can attain alone.

Subliminal fringe is absent in some strong reflexes, at least as concerns a particular muscle. That is not to say it is absent altogether, for a reflex employs concurrently several synergic muscles each with opportunity for fringe.[14] Subliminal reflexes converging with allied effect on the same muscle can produce large quantities of contraction (Eccles and Granit[15]).

The large fringes of weak reflexes are an effective factor in co-ordinative liaison and combination between such reflexes, and between them and others. Thus, nothing is more frequent than in the course of an experiment with, for instance, the ankle extensor attached to the myograph, to see, if head and neck be passively turned into the so-called favourable position, the same limb-stimulus evoke a much greater reflex than before, although the new posture of head and neck itself may have evoked no reflex from the muscle. It facilitated by means of subliminal fringe, on which summation built when the local reflex was repeated.

Thus again with Rademaker's[16] supporting reaction from the sole of the foot and soleus postural stretch-reflex. Also with Bremer's[17] cerebellar influences upon the extensor reflex of the limb; and these remind us that there can be inhibitory fringe as well, and that the withdrawal can give Hughlings Jackson's "release"; a theme so luminously treated of by Sir Henry Head. It is mainly by subliminal fringes of motoneurone excitation that the higher nervous centres exert the postural adaptations which are as necessary to the animal as is posture itself.

The "Subtetanics" Group.—An important attribute of these is that they effect grading of the reflex contraction in their motor-units by so spacing the successive contraction-waves that the integrated tension falls variously short of full tetanic. The shortage is of course greater the slower the wave-succession, and the scale of grading becomes progressively less open as full tetanus is approached. A given increment of frequency of firing of the motor-unit represents less increment of contraction-tension value in proportion as the frequency of firing in the motor-unit is already high, until at last it represents no increment at all (occlusion).[4] I suppose, therefore, the weak reflex will contain more tremor, but I do not know that myographically. The subtetanic contraction is of course tremulous. With a power-unit like that of gastrocnemius, which averages a contraction-wave of some 8 g., its tremulous contraction must threaten the steadiness of the whole muscle. But lessening such defect is the circumstance that the various subtetanized units are out of phase one with another. It may well be a specific office of co-ordination to keep them out of phase. If a number of the subtetanic units once get into step with each other, tremor must become gross. Denny-Brown has brought forward,[7] and supported from his experiments, an interpretation on this basis of the clonus readily induced in the decerebrate rigidity of the laboratory. Clonus there, he says, is simply the tonic asynchronous discharge of the units thrown into synchronism. The tonic stretch-reflex of the laboratory can exhibit in the firing of its units all shades of transition between asynchronism and complete synchronism, and it can be made to pass from one to the other reversibly by suitable conditions of initial pose (Viets),[18] and, as Pritchard[19] has particularly shown, of tension. Conducive to the position taken by Denny-Brown[20] was his identification of the "silent period" of the galvanometer string following a knee-jerk as being inhibition of proprioceptive source evoked by the jerk itself from its own muscle. This inhibition damps the discharge of the jerk down in effect to one centrifugal impulse. In clonus not only do the motor-units get into step as regards contraction, but their getting into step and their keeping in step is accentuated by their proprioceptive inhibitions getting into step likewise. Their beats in the clonus are punctuated by their proprioceptive self-inhibitions, forming a vicious circle keeping them in step. Inherent in the operation of the subtetanic motor-units is besides tremor some waste work, an uneconomy which has been dealt with by Bronk.[21] Can we be sure that nature is in love with economy? In this instance the uneconomy seems more than offset by the advantage gained in delicacy and range of means of grading reflex contraction strength.

The "Maximals" Group.—In weak reflexes—for instance, in weak postural reflexes—there may be no "maximals" at all. A weak tonic postural reflex of soleus (cat), favourable to isolated examination of single motor-units, not rarely fails to exhibit a single unit firing in other than subtetanus. On the other hand, in strong reflexes there may be none but "maximals" in the entire motoneurone pool of a whole muscle, as driven in laboratory experiment. Though this is quite exceptional. In the "maximals" group each unit yields its maximal contraction. Motor-units added mean added contraction, and removed mean contraction lessened. All additional excitement received here lays aside its mechanical equivalent. That is to say, "occlusion" occurs here, and is therefore prominent in strong reflexes. It is the "maximals" group which by its growth limits more and more the further increase of the reflex muscular response. It brings into the relation between increase of reflex contraction and increase of reflex stimulation some resemblance to the approximately logarithmic ratio between increment of sensation and increment of stimulus. The maximals are economical in a sense, because contraction-tension is maintained at a smaller expenditure of energy in a stronger contraction than a weaker.

THE MOTOR CENTRE AS A SUMMATION APPARATUS

I would not pursue the subject to tiresome length. It arrives at this: that the motor centre—to use that old but expressive term—is more than a mere relay on the way out to its muscle, more than a mere passive place of assembly for motor-impulses directed thither. It is a central instrument which deals with those impulses actively, and adjusts *actively* the contraction-strength of its reflexes; it works on the basis of the "central summation process."[11 12] Driven and fed by centripetal impulses, it submits them to the summation process. It is in short a "summation-mechanism." It operates on the individual motoneurone by intensity-summation; it exerts a whole scale of grades of excitement on it. It also, it is true, operates partly on the basis of extensity-changes, since it varies the number of motoneurones it engages. But since central impulses in order to excite a motor-unit must be summated, the central mechanism is ultimately wholly a summation apparatus. One secret of its co-ordinative power lies in its ability to summate with almost negligible time-lag shifting fringes and mobile shades of excitation that meet and overlap upon it. These join and disjoin, expand and shrink, as afferent channels leading from various sources come into or drop out of action; and each and every time the central apparatus subjects them to or releases them from its summation. It is an apparatus developing a greater range of intensities both upward and downward than the muscle-fibres which it operates can with their tension follow. If this seem wasteful of central nervous energy, we may remember that additional excitation exerted on a motor-unit, already driven "maximally" for tetanic contraction, is not necessarily wasted. That surplus remains still a contribution to co-ordination, because further excitation offers a further resistance to inhibition;[11 31] just as an added inhibition in the case of an already quiescent neurone, although in one sense wasted, is a further protection (which

co-ordination may need) against excitation. In times of crisis the dilemma lies between strong actions, and the very strength of the action taken may serve to safeguard it from extrinsic interruption.

CONCEALED REFLEXES

Quantitative adjustment of amount of contraction seems to first thought a function purely quantitative. Yet because strengths of contraction may affect and shift the scope of an act, contraction-strength can acquire a value which is qualitative. The laboratory plan of obtaining reflexes by direct stimulation of bared afferent nerve is for some purposes excellent. But it is an artificiality, and certain reflex artificialities derive from it; among them this, that each large afferent nerve presents a dominant reflex which may conceal other reflexes. This dominance is itself a compromise, although often an overwhelming one, between conflicting reflexes. To display natural reflexes thus submerged we have to turn to localized stimuli natural for them. In this way can be traced the otherwise concealed ipsilateral extension reflex of the limb, and its broad quantitative course can then be followed. It activates the great extensors of the limbs. It enters into that complex of reflexes which works the limb as a tool for standing and locomotion.

[After dealing with this point at some length, the lecturer then proceeded]

REFLEX POSTURE

The importance of posture is alluded to sometimes by saying that it is the starting point and the end point for every movement. But, as Ramsay Hunt remarks, reflex posture "accompanies movement like a shadow."[22] Stanley Cobb[23] writes that they "coalesce and often cannot be separated"; illustrating that well is an example of reflex posture familiar in the laboratory. In cat and dog, the brain having been entirely removed, the scratch reflex is easily evoked. A minute localized stimulus, applied for instance behind the ear, provokes scratching from the same hind foot. A stigmatic electrode, in the form of a tiny gilt pin, such as entomologists use, inserted perhaps a millimetre deep into the skin among the hairs, conveys a faradic current barely strong enough to be felt when applied to one's tongue. This stimulus—a make-believe flea—excites the reflex, probably via nerve-endings round the hairs, for after removal of the hairs the reflex is difficult to get. The co-ordination of the reflex, although the preparation is merely spinal, is extensive. The limb is flexed, bringing the foot toward the ear. The digits perform a regularly rhythmic combing movement: there is a similarly rhythmed extension of ankle; the rhythm at ankle involves alternate contraction of extensors and flexors; each beat consists of a short tetanic contraction followed by a pause of quiescence; there is similarly timed but slighter rhythmic flexion of knee. Alongside this, and just as much a part of the reflex, is maintenance of a flexed posture[24] of the limb as a whole; moreover, the body is kept steadily incurved to the stimulus side, the neck deviated, and the head partly turned back, so that the foot more readily may reach it. All these latter are quite steady reflex postures. Some of the muscles engaged in the rhythmic movement are engaged in posture as well as in movement, posture and phasic contraction together in the same muscle. The co-ordination instances the way in which posture not merely alternates with movement, but accompanies it "like a shadow."

In this spinal condition of the reflex its co-ordination presents two defects. The scratching foot, although it may get near to the faradized skin-point, does not actually reach it; it scratches in the air. Further, scratching movement, which is not wanted until the limb has moved to the place, begins first of all.

The field of muscles engaged by the reflex is wide, and that is characteristic of all tolerably perfect reflexes. When giving isolated consideration to the great extensor muscles of the limbs and following their grades of reaction in the reflexes of standing and running, the concomitant reflexes which contribute likewise to the standing, etc., of the limb are omitted in order to simplify. Similarly, a chart, illustrating a reflexly excited motor centre, pictures the motoneurone pool of a single muscle; whereas even the simplest flexion reflex excites several muscles. Lorente di Nó,[25] recording graphically the contractions of the individual eye muscles, shows that every labyrinth-reflex acting on the eyes employs the whole twelve muscles. With the flexion reflex of the limb excited from any afferent nerve of the limb the flexion is plurimuscular from the threshold up. Thus, with a small digital nerve at minimal stimulus the muscular response starts simultaneously in the ankle-flexors and knee-flexors together, and so on. From the point of view of the spinal reflex, motor-units of a muscle have motor-units in another and even distant muscle closer akin reflexly to themselves than are most of the remaining motor-units of their own muscle. The simplest spinal reflex thinks, so to say, in movements, not in muscles.

CENTRAL REFLEX RHYTHM

Hence the tiny stimulated skin spot in the spinal scratch reflex brings into action a whole array of muscles. In the spinal cat—of course, a wholly insentient preparation—they can be freely laid bare and examined naked in their activity. Without exhaustive search we soon reach 36;[21] 19 in rhythmic action at five beats a second, 17 in steady, that is postural, action. The rhythmic beating in the rhythmic ones is not a "subtetanus"—that is, not a series of twitches: each beat is a brief tetanus followed by a pause of quiescence, often long enough for complete relaxation from the tetanic contractions. The rhythm is not generated in the skin nerve-ending—the hair-endings—for it occurs on faradizing the afferent nerve itself, and indeed quite easily by electrical stimulation applied to the cut cross-surface of the top of the spinal cord itself.[26] Nor is it a rhythm developed, as was suggested above for clonus by a retropulsive effect from the operating muscles themselves; that is clear because the reflex persists after the whole of the scratching limb has been desensitized by severance of its posterior nerve-roots. The rhythm is clearly of central origin, with its seat in the hind-limb region of the cord.

The scratch reflex has of course merely a type interest. It does not stand alone in its unexpected degree of independence of local peripheral reflex guidance. Several of these central lower mechanisms, and even some seemingly higher ones, exhibit a similar feature.

It is surprising to find the movements—for instance, those of arm and hand—evoked by stimulating the motor area of the cerebral cortex not obviously impaired by complete desensitization of the limb itself. For willed movements the upset of them in every respect, except perhaps power, following on complete desensitization of the limb, is extreme. The limb is practically useless, for prehension quite so. The animal quickly treats it as useless, or indeed as worse than useless; it attempts to get rid of it by destroying it. Yet, when the motor cortex is examined by stimulation, not only does it evoke in the de-afferented arm and hand its customary movements as readily as usual, but those movements reveal no obvious departure from their usual co-ordination either as compared with experience of them in normal monkeys or with the movements evoked by corresponding cortical stimulation in the opposite normal fellow limb. It seemed so to Mott and myself[27] in our observations now long since. It has seemed so again to Dr. Denny-Brown and myself, applying recent myographic and galvanometric technique to samples of some of the muscles under cortical activa-

tion. Therefore, wild inco-ordination under willed action, and little or none under the action of the directly stimulated motor cortex. One may relate this contrast to the probably very direct play of the pyramidal tract upon the motoneurones.[28 29] The contrast is at least a caveat against accepting the movement excited electrically from the motor cortex as a close homologue of a willed one. It seems as unimpaired by desensitizing its limb as is the spinal scratch reflex itself.

REFLEX STEPPING

The same thing is met with in the stepping reflex, and to such an extent that Graham Brown[30] argues, from his observations, that the stepping is a centrally initiated and executed cyclic reflex essentially independent of—although modifiable by—peripheral stimuli. It certainly often occurs quite in absence of all plantar or foot stimuli—for instance, in the air or with all four feet wholly desensitized. The stepping reflex, like the scratching reflex, can be excited by weak stigmatic unipolar faradization from the cut cross-face of the spinal cord[26] at a tiny area in the lateral column, the stepping being, for instance, in the hind limb, and the point stimulated at the top of the cord, the preparation being decapitated. The weak faradic stimulus excites in the hind limb of the same side stepping which from walking becomes running as the stimulus is made less weak. There tends to be the accompaniment of feebler stepping by the opposite hind limb; and this crossed accompaniment agrees in rate with that of the fellow limb, but is oppositely timed so that it alternates in phase with it, as in natural locomotion. By arranging two electric circuits two stigmatic electrodes can be used with separately adjustable strength of stimulation. If then the right and left points are stimulated concurrently on the cut face of the top of the cord a subliminal stimulation of one is found to become effective on applying a subliminal stimulus to the other. Galloping can be obtained by stimulating the two points concurrently with somewhat stronger stimuli. The stepping point lies in the deep dorsal part of the lateral column. If while the stepping is in progress under excitation of this point a weak stigmatic faradization be applied to the ventral part of the ventrolateral column of the same side the stepping at once slows down or stops. Stimulation at this point when the dorsolateral point is not being stimulated will give extension of the same side hind limb. The dorsal point I mentioned as the "stepping" point; the ventral point might be called the "standing" point. As yet I have examined it only at the above-mentioned level. The right and left ventral column points when concurrently stimulated reinforce each other. The observations occur equally well with the stepping limb suspended—that is, with the proprioceptive stimuli in the stepping limbs quite otherwise than when the limb is bearing superincumbent weight, also quite without plantar stimuli, the feet being in the air. This complex cyclic act with the various timings of its sequence, as initiated and maintained by excitation of a slender descending intraspinal channel from above, seems strangely independent of guidance or support from local centripetal factors in the limb itself. Stimulation at the stepping point in the lateral column starts the limb stepping and keeps it going practically at what pace it likes. Stimulation of the antagonistic descending path slows the stepping, and if stronger stops it and changes it into standing. All this just as well with the limb merely hanging in the air. With stepping and standing as incompatible opposites for the limb, this instance, where the reaction deals with the limb on large lines and suppresses one of the incompatible acts to bring in the other, offers analogy to reciprocal innervation. It gives, further, an illustration of a feature of co-ordination on which I have perhaps with wearisome insistence dealt with elsewhere—namely, that for a muscle or a muscle-group to be contracting does not exclude the being under inhibition. If we glance back, for instance, at our picture of the excited motor centre, and take it a stage further by inserting some inhibition, we see at once that the inhibition, counteracting according to its degree less or more of the excitation, can slacken or stop the firing of some or all of the discharging motoneurones. Only in the extreme grade which stops all the motor-units will the inhibition reveal itself as a complete absence of contraction of the muscle or muscle-group.

CONCLUSION

But I must not detain you longer. The present seems to me a time of unusual promise for neurological investigation both in the clinic and in the laboratory; a time which for that reason calls for close liaison between them. For such liaison to be effectual the two have to lie near at hand one to another. The laboratory, in a word, has to be on the spot. Apropos of this, if I dare think aloud, there is a reflection which is natural on this occasion. Where in all the world could be a more fitting point for such liaison, for such contact, than at the institution which, with its noble tradition of teaching and research, holds with peculiar claim within its portal the bust of the great master to whom our lecture to-day seeks to pay commemorative tribute, Hughlings Jackson?

I have dealt very imperfectly with a small bit of a large problem. I have kept too much within the purely experimental laboratory. The smallness of the piece is disheartening. The problem itself has the interest that large as it is—to speak *more Hibernico*—it is larger still. Hughlings Jackson in his writings turns back and forth between muscular co-ordination and mental experience as if for him they were but aspects of a single theme. It may be that to decipher how nerve manages muscle is to decipher how nerve manages itself. If so, not without significance may be what we have just glimpsed: that there are in the nervous system heights of excitation and depths of inhibition higher and deeper and with grades of adjustment ampler than muscle despite all its subtleties can commensurately express.

FRACTURE OF THE SKULL IN CHILDHOOD*

BY

JOHN T. MORRISON, O.B.E., F.R.C.S.

HONORARY SURGEON, ROYAL SOUTHERN HOSPITAL; HONORARY ASSISTANT SURGEON, ROYAL LIVERPOOL CHILDREN'S HOSPITAL

AND

MIRIAM ROSKIN, M.B., CH.B.

CASUALTY OFFICER, ROYAL LIVERPOOL CHILDREN'S HOSPITAL

Children are so often in trouble as the combined result of youthful spirits, naughtiness, and inexperience, that a knowledge of the consequences of their everyday injuries should be the subject of careful inquiry. In the matter of head injuries the opportunity has occurred of studying a series at the Royal Liverpool Children's Hospital. The findings are of interest, not only from the academic point of view, but also from that of the general practitioner in his daily round, and in certain medico-legal aspects. We have not tried to deal with the subject in any exhaustive or systematic fashion, but have dwelt, as fully as the material at our disposal seemed to justify, upon those points which are not in accordance with accepted teaching, or upon which opinion has not yet crystallized. In many instances the statements in the literature are exceedingly confusing and often contradictory.

Frequency of Fractured Skull

The period covered by the present survey is approximately two years. During this time fifty-seven cases of fractured skull have been admitted to the City Branch of the Children's Hospital. In a corresponding period at the Royal Southern Hospital, with roughly twice as many beds, only twenty-five adult cases were dealt with. Further, in the course of the same two years the city coroner (Dr. G. Cecil Mort, whom we have to thank for his courtesy and assistance) held inquests on thirty-nine children under 12 in whom death was caused by fracture of the skull. Of this series our own ten fatal cases no doubt form part. It would appear that the elasticity of the growing bone, which is credited with saving so many youngsters from serious injury, is by no means so adequate a safeguard as has been supposed. At any rate the cases in which it has failed to protect the child—often a very young child—from fracture of the skull are not uncommon at a busy children's hospital. The youngest in this series was only 1 month old. Obstetrical fractures have not been included.

Fractures of the Base

In the past it has been accepted that "basal fractures are unusual in children."[1] Kirmisson[2] says: "In children we very rarely see fractures of the petrous part of the temporal bone and symptomatic bleeding from the ear." Very possibly these injuries are increasing in number with the growing frequency of motor accidents. In this series there are no fewer than twenty-two (38.6 per cent.) in whom the diagnosis of "fractured base" was made either upon the evidence of the escape of blood or cerebro-spinal fluid from mouth, nose, or ears, or from *x*-ray examination. In the hands of competent observers these grounds are adequate. Radiography, although of the greatest assistance, gave positive findings in sixteen cases only. In two the report was "doubtful." In four it was "negative," but in one of these the presence of a basal fracture was definitely proved post mortem.

* A paper read before a meeting of the Denbigh and Flint Division of the British Medical Association.

Causes of Fractured Skull

It is regrettable, though hardly to be wondered at, that twenty-four out of the fifty-seven cases were the result of injuries by motor vehicles, while out of the fatal cases investigated by the coroner 87 per cent. were due to the same type of trauma. The causes of the remainder make motley reading. Sometimes the children arrive at hospital grossly shocked and bleeding from mouth or ears. Sometimes they are only brought up some days later with vague complaints or with a local bruise or haematoma. Without *x*-ray evidence no one would dare diagnose the extensive fractures that are sometimes found. Relatively slight injuries are capable of giving rise to fractures of the skull in childhood. In one case no history of trauma could be elicited. The following table reveals the very serious results that sometimes follow what appear to be minor accidents. Of necessity the term "relatively slight" is an elastic one, but it is obvious that in many instances the injuries are only such as are not uncommon in ordinary households.

No. of Case	Age	Nature of Accident	Symptoms on Admission	Local Signs	X-ray Report
5	3 mo.	Mother fell with baby against bedpost	Nil	Depression palpable	No *x* ray
18	11 yrs.	Fell down "a few" steps	Dazed, headache.	Bleeding from ear	Fracture, occipital.
22	4½ yrs.	Fell off table some days before admission	Headache	Oedema	Crack, occipital
31	7 mo.	Fell down five or six steps	Nil	Slight bleeding, nose; oedema over eyes	No *x* ray P.M. fractured skull.
40	13 mo.	Fell out of pram some days before admission	Nil	Haematoma	Crack, parietal
41	6 yrs	Fell off 6 ft. wall day before admission	Two hours unconscious; vomited; headache.	Tenderness	Crack, occipital
42	6 yrs.	No history of trauma	Headache, drowsy; vomiting.	Haematoma	Fracture, parietal
47	11 yrs.	Ran into tight rope and fell back	Shock	Nil	Crack, parietal
48	7 mo.	Mother fell with baby	Nil	Oedema and tenderness	Very extensive fracture.
50	6 yrs.	Fell down some steps	Very drowsy	Nil	Fracture, occipital.
51	1 mo.	Fell off bed	Nil	Haematoma	Extensive fracture.
52	17 mo.	Fell, and mother fell over him, two days before admission	Nil	Haematoma	Fracture, occipital
53	7 yrs.	Fell off a wall	Nil	Swelling, forehead; subconjunctival haemorrhage	Crack, frontal
57	—	Knocked down by bicycle three days before admission	Persistent vomiting	Nil	Linear fracture

Chief Symptoms and Signs

The cardinal symptoms in these cases are three—namely:

1. Vomiting.
2. Impairment of consciousness.
3. Bleeding from mouth, nose, or ears. In a few, cerebro-spinal fluid was also found to be escaping.

Vomiting occurred in practically three-quarters of the cases (77 per cent.). It was sometimes very persistent. In a few instances it was only after the lapse of a day or two that it began to be troublesome. Where fracture of the skull was absent, but where concussion or unexplained shock suggested the possibility of that diagnosis,

the percentage of cases with vomiting was appreciably lower—namely, 48 per cent. instead of 77 per cent.

Second in point of frequency comes impairment of consciousness; it was recorded in 66 per cent. of our fracture cases. During the same period seventy-four patients were admitted suffering from this symptom in whom no fracture was found. In other words, out of 112 patients suffering from some degree of impairment of consciousness about one-third (33.9 per cent.) proved to have fractures of the skull. The symptom varied from a transient dazed state to deep coma. It probably occurs much more frequently than is reported, because many of the patients are babies or young children, in whom minor manifestations of this condition are not appreciated by the lay observers present at the time of the accident. In 71 per cent. of fracture cases showing impairment of consciousness there was associated vomiting or else bleeding from mouth, nose, or ears to help to confirm the diagnosis.

There remain nineteen cases in which no impairment of consciousness was actually recorded. The leading signs and symptoms in these nineteen may be tabulated as follows:

Vomiting and bleeding from mouth, nose, or ears ...	8
Vomiting and local signs of injury to head	2
Palpable depression of the skull	2
Local oedema and tenderness only	7

It will be seen, then, that in the majority of cases (fifty out of fifty-seven), the history of trauma involving or possibly involving the head being given, where fracture of the skull has occurred, symptoms are present which in the light of the present investigation are strongly suggestive, if not diagnostic, of that lesion. In association with one or more of the three cardinal symptoms, local signs are of the greatest significance.

Mortality

The general mortality in the fifty-seven cases was nearly 18 per cent., but when the twenty-two cases of basal fracture are considered by themselves it is found that the death rate leaps up to the very grave proportion of one in three (32 per cent.). The immediate cause of death is set out in the following table:

Irremediable brain damage	6
Meningitis	3
Brain damage and sepsis	1

Of the first group the average stay in hospital before death was a matter of a few hours only, and such cases must be regarded as hopeless on account of the severity of the primary injury. The meningitis cases are those in which a fracture of the base was followed by an infection from the nasopharynx or the associated air passages, and a generalized spread to the meninges. The organism recovered by lumbar puncture was the pneumococcus in all cases, complicated in one individual by the presence of a streptococcus. In one of the pneumococcal cases there was a scarlatiniform rash thirty-six hours after the accident. It is possible, of course, that this was a pure coincidence, and that the child had been on the point of developing scarlet fever when the injury occurred. The trauma was relatively slight, and it was noted on admission that the child appeared lively and well. In one or two such cases of pneumococcal meningitis following unsuspected basal fracture we have seen recovery take place, but not within the present series. In the meningitis cases death occurred on the third, fourth, and ninth days respectively. No instance was seen of the late formation of an intracranial abscess. The patient whose death was attributed to brain damage and sepsis was very grossly injured. There was laceration of the dura and ultimately a *hernia cerebri*. He did not come directly under our control, and no primary operation was done. It is very doubtful, however, whether in any case he would have survived.

Treatment

All cases of head injury should be regarded as possible cases of fracture of the skull. The suspicion should also arise in children seen suffering from shock not otherwise adequately explained. During the period under review 181 such cases have been admitted, and of these, fifty-seven —that is, more than 31 per cent.—were found to have bone damage to the skull. It has been our practice to keep these fracture patients recumbent for ten days to a fortnight, and to advise mental quiet and physical rest for a further week, even in the milder cases. In all cases of fracture of the base of the skull our findings would suggest the advisability of a dose of antipneumococcal serum—and possibly antistreptococcal serum also—as early as may be after the injury.

Where an open wound exists early operation is imperative after treatment has successfully coped with the primary shock. Local anaesthesia is the method of choice, even in small children. Operation was performed in four cases. In three there was a compound fracture of the vault with depression of fragments; in one a large depression without open wound. Our methods are as follows: after infiltration of the subcutaneous tissues right down to the pericranium with 1/2 per cent. novocain and 1 in 1,000 adrenaline (mviii ad ʒj), the edges of the wound are excised down to bone. The exposed bone is then painted with iodine. A small trephine may now be necessary, but in most cases it is possible to nibble away with fine gouge forceps an overhanging edge till access is gained to the under surface of the depressed fragment, which can then be elevated. Even fragments completely separated may be preserved. They contribute materially later on to the soundness of the skull. In no case in this small group did such fragments interfere with primary healing. In all four, convalescence was uninterrupted and recovery complete. Drainage was not required. In one case transferred from another institution it was found that a scalp wound over a small depressed fracture had been sutured without any operative cleansing. It was grossly infected, and the child was dangerously ill. The wound was opened up and antistreptococcal serum given, fortunately with excellent results. For those cases where a small depression exists, perhaps as large as the tip of the little finger, operation has not been considered necessary in the absence of an external wound. It is the routine practice to elevate the head of the bed, and when symptoms of increasing intracranial pressure ensue in the shape of slowing pulse and increasing drowsiness, attempts are made to counteract them by rectal injections of 10 per cent. salt solution. If this fails pressure is relieved by lumbar puncture, repeated if necessary. It is appreciated by us that the effect of this is only temporary, but we believe that extensive operations designed to give more permanent relief are not justifiable.*

Prognosis

This question is naturally of the greatest importance, quite apart from its increasing significance from a medico-legal point of view. In many quarters it is taken for granted that the chances of unpleasant sequels after head injuries in children are very small. In others the prospects of grave mental defects and epilepsy are altogether unduly stressed. A careful "follow-up" of our patients has shown that in approximately 50 per cent. of

* In the thirteen consecutive cases treated since the writing of this paper no single death has occurred. Included in this number have been four fractures of the base and three depressed fractures of the vault, two of the latter being compound.

the thirty-three whom we have been able to trace there have been departures from normal ; thirteen were stated to suffer from headaches, and of these, four also showed signs of increased nervousness in the shape of twitching, starting when spoken to, or speech defects. One was described as " very excitable." In one case the child's behaviour was found to have deteriorated, and one was said to be less intelligent. Two children suffered from unilateral facial paralysis following the accident, but in both cases recovery took place, in one completely in two months, but in the other slight drooping of the eyelid remained after nine months. In two some deafness occurred.

In an admirable paper devoted to this subject Beckman[3] tells us that all such patients recover within two years, with the exception of perhaps 5 per cent. Nevertheless the unexpectedly high percentage of unpleasant sequels emphasizes the importance of prolonged rest. Beckman makes no reference to the development of epilepsy, and apart from convulsions noted shortly after the infliction of grave brain injury, and usually speedily fatal, we have seen no evidence in children of this complication. It must occur very rarely.

Conclusions

1. Fracture of the skull occurs in childhood much more frequently than is supposed.

2. It often results from apparently trivial injuries.

3. Fracture of the base is not uncommon, and is of very grave significance.

4. Sepsis must be forestalled by operative cleansing in compound fractures of the vault and by the prophylactic use of serum in fractures of the base.

5. Medical measures should be taken to prevent undue increase of intracranial pressure.

6. In view of the proportion of sequels prolonged rest is indicated.

A SWIFT AND SIMPLE METHOD FOR DECIDING PNEUMOCOCCAL "TYPE"

BY

RICHARD R. ARMSTRONG, M.D., F.R.C.P.

(From the Research Laboratory, St. Bartholomew's Hospital)

Increasing attention has been paid during the past year to the treatment of lobar pneumonia by concentrated antipneumococcal serums.[1] The serum available from American sources (Parke, Davis and Co., and Lederle) is divalent and effective against the pneumococcal Types I and II. A supply of Type I antiserum will probably soon become generally available from the Wellcome Research Laboratories. I am at present engaged on the treatment of selected severe cases of lobar pneumonia with each of these serums.

While there is some doubt about the usefulness of Type II serum, there is good reason to consider the Type I serum of real therapeutic value. In these circumstances, the determination of the type of pneumococcus responsible for a given case of lobar pneumonia becomes a matter of urgency, first in the interests of the patient and, secondly, to avoid waste of the very costly serum.

A swift and simple method for deciding pneumococcal type is as follows. Type may be ascertained within four hours from the time of collecting sputum, or lung puncture fluid when sputum is not immediately available; other pathological material containing virulent pneumococci may, likewise, be used.

A suitable sample of sputum is chosen and emulsified in a watch-glass with an equal volume of broth. Half a cubic centimetre of the emulsion is inoculated into the peritoneal cavity of a mouse. Four hours later the peritoneal contents are sampled by aspiration in the following manner. The mouse is grasped by the scruff between the finger and thumb of the left hand ; at the same time the animal's tail is firmly held against the inner side of the palm of the hand by the third and fourth fingers. The abdomen is thus conveniently exposed and explored by means of a 1 c.cm. Record syringe with fine No. 18 rustless steel needle attached. The barrel of the syringe should be held by the third and fourth fingers of the right hand against the palm, and the plunger lifted by the right thumb and index.

Four droplets of the peritoneal exudate thus obtained are expressed on to slides, appropriately marked with grease pencil to correspond with the three chief pneumococcal types and control ; the droplets are at once mixed with a platinum loopful of Types I, II, and III agglutinating serums and rabbits' normal serum. The drops are covered with cover-slips as soon as mixed, and examined at once under the microscope, using a No. 4 ocular 1/6 inch objective with plane mirror reflector, the condensor being removed. Focusing is facilitated by the grease pencil marks on the slide.

The immediate result, in the case of a positive reaction, is a conspicuous increase in size of the pneumococci, due to conjugation of coccus and homologous antibody. Brownian movement is retarded, and the pneumococci become very apparent as lanceolate bodies, surrounded by a clear, highly refractive capsular zone. Agglutination soon follows, but is accelerated if the slide is warmed on the floor of the 37° C. incubator for three to five minutes, and then again examined.

The end-result of the reaction is the aggregation of masses of agglutinated pneumococci and leucocytes ; the pneumococci, sensitized by conjugation with the antibodies, are chemotactic to the phagocytes and polymorphs present in the peritoneal exudate. This characteristic reaction is seen only when virulent pneumococci are effective, belonging to the recognized serological types. The result, at times, may be a little obscured by the presence of undigested debris from the sputum, if exploration of the mouse's peritoneum is attempted too soon or the initial dose of sputum is too large. The rate at which the peritoneal cavity deals with this foreign material varies somewhat in different specimens of sputum.

The test may be carried out with equal facility at any interval exceeding three to four hours, which period, generally speaking, represents the minimum time required for sufficient multiplication of the virulent pneumococci injected and digestion of the sputum.

The agglutinating serums used have a titre of 1 in 40, and are prepared by immunization of rabbits with representative type strains, isolated from recent cases of adult lobar pneumonia. The precaution of identifying both strains and serums by agglutination and absorption tests against the standard Rockefeller types has been observed always. Macroscopic agglutination has invariably confirmed the results of microscopic tests. The microscopic method is not only simpler and more rapid, but also considerably more delicate than the macroscopic, besides being economical of serum. The advantages are such that I now use this method alone.

I make no claim that the method described here is original ; the object of this communication is to make it widely known. The subject is reviewed by A. B. Sabin,[2] to whom the credit is due of applying rapid methods of typing pneumococci. Sabin's procedure is very similar

to that described, save that the specific agglutinating serums are diluted to eliminate coagglutinins and that smears of the mixed pneumococcal exudate and serum are made on slides, dried and stained. Sabin's method therefore sacrifices the opportunity of observing the striking and entirely characteristic change in the appearance of the cocci which follows conjugation with the specific antibody-bearing protein; and, further, his method introduces additional manipulations in the preparation, drying, and staining of the films. Neufeld, twenty years ago, applied the microscopic method to typing pneumococci, but was dissatisfied with the results he obtained with Type III. In my experience, however, no difficulty has arisen so far with this organism or with material from cases of Type III pneumonia. In any event the results with Types I and II are decisive, and are the key to early treatment.

The experiments described here have been carried out with the assistance of the Medical Research Council.

THE ENIGMA OF THE CHILBLAIN

BY

RUPERT HALLAM, M.D.

PHYSICIAN, SKIN DEPARTMENT, ROYAL INFIRMARY, SHEFFIELD

The discomforts and disabilities caused by chilblains during the winter are very real, although non-sufferers may regard the complaint as trifling. We have but a fragmentary knowledge of the subject; it is known that cold is the exciting cause, but how one individual escapes and another suffers has never been determined. Consequently it is improbable that efficient means of prevention will be found until more is known of the etiology and pathology of the condition.

The Etiology of Chilblains

Perniosis is essentially an affliction of youth, as the following analysis of 100 consecutive cases shows:

Age	Number of Cases
0–10	54
10–20	29
20–30	4
30–40	5
40–50	4
50–60	3
60–70	1

From the above it is evident that after a period of years an immunity is acquired. Certain persons are free in their early years, but suffer in middle age; strange to say, however, chilblains are seldom met with in the aged, even when serious organic disease is present.

A histological examination in the early stages shows that there is a rapid degeneration of the small vessels, accompanied by perivascular infiltration. There is not a mere transudation of serum, as some writers would have us believe, but a sudden and severe damage affecting the vessels of the papillary layer of the cutis. Attempts to produce a chilblain experimentally by the application of solid carbon dioxide, injection of histamine, etc., have failed. In a susceptible individual a chilblain commences to make its appearance about eighteen hours after exposure to cold of the requisite severity. Should the temperature remain low little alteration in the state of the chilblain ensues, but a change of wind bringing a warmer atmosphere produces a rapid amelioration of the symptoms, and the chilblain disappears with surprising rapidity. Change of environment may also produce a striking alteration in individual susceptibility. These facts are of importance, for it is not unlikely that they explain the reputation of many of the so-called cures for chilblains.

Chilblains Associated with Other Diseases

In order to investigate some of these suggestions, I endeavoured to ascertain the relative frequency of chilblains in certain diseases of known etiology, and also to determine the incidence in various social states. A more detailed account of these inquiries has been given in a previous communication.[1] The incidence of chilblains among patients attending the casualty department of the Sheffield Royal Infirmary compared favourably with that of others in more affluent circumstances. On the other hand, statistics obtained from the medical out-patient department and from the tuberculosis dispensary in the same city indicate that the incidence rises with a disturbance of the general health, as shown below.

	Percentage Affected with Chilblains
1,000 casualty patients	5·3
1,000 medical patients	9·2
1,000 tuberculosis patients	13·2

The figures in the last group are of particular interest; for some writers, among them Darier,[2] allege that the chilblain is actually a tuberculide. Although the above figures give some support to this theory, it is probably more accurate to assume that tuberculosis and some other diseases which impair the general health are predisposing causes. An analysis of 1,275 patients attending the medical out-patient department affords some interesting comparisons. Taking first the abnormalities of the circulatory system, 14 of my series had various degrees of arterio-sclerosis, yet in no instance was there a history of concomitant chilblains. On the other hand, of 86 suffering from some form of heart disease there was a record of recent chilblains in 15—that is, 17.4 per cent. From these figures it appears that a gross defect in the arterial wall may exist without materially diminishing the vitality of the capillary. The frequency with which chilblains are met with in disorders of the heart may be accounted for by the lessened propulsion force, and consequent slowing of the blood stream, interfering in some way with the nutrition of the superficial vessels. An examination of patients suffering from some definite imperfection of an endocrine gland is instructive. Among the 1,275 patients referred to 12 were suffering from myxoedema, but none suffered from chilblains; 24 were under treatment for exophthalmic goitre, of whom 3 had had chilblains since the onset of hyperthyroidism; this appears to show conclusively that chilblains are not necessarily associated with excess of thyroid secretion.

"Chilblain Circulation"

Most observers will agree that many chilblain subjects exhibit some peculiarity of the peripheral circulation in winter time. This was confirmed by an investigation of 100 cases of chilblains, for of this number 51 showed an apparently abnormal circulation in the hands and feet. It must be admitted that the records are of little intrinsic value, for it is impossible to define what is meant by normal blood supply. Under varying conditions the subjects might show different responses to heat and cold; furthermore, it is incorrect to assume that the peripheral circulation is necessarily normal because it appears to be

so clinically. Of the 51 cases showing clinical manifestations of variation of the circulation from the normal, the most obvious signs were cold hands and feet, accompanied by cyanosis of the hands and the lower third of the legs—a state of the peripheral circulation which is not infrequently referred to as the "chilblain circulation." What is the pathology of the abnormal response to cold? A histological examination of the skin from such a cold blue hand, even where there are no chilblains, shows some thickening of the walls of the smaller vessels. It is agreed that cyanosis and coldness indicate a slowing of the blood stream. Krogh[3] states that the temperature of the skin is primarily determined by the rate of blood flow, which in turn depends on the state of contraction of the arteries and arterioles. As the shade of the skin is controlled by the state of the subpapillary venous plexus and capillaries, it is obvious that these small vessels must be dilated in perceptible cyanosis. This is confirmed by an examination with the capillary microscope, a method of observation which is unfortunately very limited, for, excepting in the nail folds and lip, it is not possible to see more than a small section of a capillary loop. On examining a pronounced case of this type of cyanosis, the investigator almost instinctively presses the dorsum of the cold blue hand, which fills in slowly from the periphery like a closing diaphragm. In the individual with hands of normal colour, however, the white patch reddens from below as well as from the periphery. The only reasonable explanation of this interesting phenomenon is that first there is a closure of the arterioles, and secondly a return flow of blood from the neighbouring superficial venules. Spalteholz pointed out that there are no valves in these venules, consequently there is no obstruction to the return along them; but the blood cannot reach the venules from the veins in the deeper layers owing to the presence of valves. Again, if the ulnar half of the hand is immersed in hot water it gradually becomes red, whereas the non-immersed portion retains the original cyanotic colour. The line of demarcation is very sharply defined, indicating that the large arteries are not involved. It appears, therefore, that the cyanosis and colour is accounted for by a constriction of the arterioles, together with a dilatation of the capillaries and subpapillary venous plexus. Although this type of circulation is frequently encountered in patients who are subject to chilblains, it is certain that this peculiar pathological change alone will not produce a chilblain, even with an accompanying exposure to cold, for in the syndrome known as acrocyanosis an extreme degree of cyanosis and coldness of the extremities may exist without the slightest evidence of a chilblain. At the same time, it must be admitted that a high percentage of acrocyanotics do suffer from chilblains. Again, in Raynaud's disease, which Lewis[4] has shown to be a spasmodic arrest of the circulation due to a contraction of the digital arteries, chilblains are not commonly met with. The etiology of the chilblain is therefore still obscure. It appears that there must be an unknown and independent factor producing a change in the wall of the smaller cuticular vessels, in addition to the factor which causes slowing of the blood stream. This change in the vessels is necessary before the exposure to cold is able to damage the tissues, for in normal skin, as Lewis[5] has pointed out, even after the skin has been sufficiently frozen to form a wheal, the capillaries are afterwards found to be intact.

Biochemical Investigation

The anticipation that biochemical investigation would advance our knowledge on the subject has, unfortunately, not been realized. In view of the fact that calcium salts inhibit the transudation of serum through the capillary walls, and as a result also of belief in the existence of a diminished coagulability of the blood in chilblain subjects, calcium therapy has been singularly popular for many years. It is significant, however, that Percival and Stewart[6] find the serum calcium normal as regards both quantity and quality; moreover, these workers also ascertained that the ingestion of calcium salts in quantities usually prescribed does not appreciably raise the amount of serum calcium.

The Blood in Perniosis

My investigations of the blood in both chilblain subjects and acrocyanotics does not support the contention that the coagulation time is delayed. The method of estimation adopted was that of Dale and Laidlaw. The first drop of blood was always selected, and the test was repeated three times. The tubes were immersed in water at 37° C. The following table shows the average time.

Blood Coagulation Time

Ten chilblain patients: 2 min. 16 sec., 2 min. 36 sec., 2 min. 10 sec., 2 min. 26 sec., 2 min. 6 sec., 2 min. 29 sec., 2 min. 9 sec., 2 min. 7 sec., 2 min. 10 sec., 2 min. 3 sec.

Ten acrocyanotic patients: 1 min. 58 sec., 2 min. 18 sec., 2 min. 15 sec., 2 min. 2 sec., 2 min. 52 sec., 2 min. 8 sec., 2 min. 27 sec., 2 min. 38 sec., 2 min. 31 sec., 2 min. 5 sec.

Six normal controls: 2 min. 18 sec., 2 min. 10 sec., 1 min. 55 sec., 2 min. 19 sec., 2 min. 8 sec., 2 min. 11 sec.

Taking into consideration the work of Percival and Stewart, as well as the above, it is doubtful whether there is an adequate reason for the belief in a calcium deficiency.

In consequence of the recently acquired knowledge relating to the influence of vitamin D on the development of bone and teeth in youth, and also of the important function of the accessory food factors in the prevention of disease, it is important to know whether changes in the peripheral vessels may be attributed to a deficiency of one or more constituents of the diet. It has been found, however, that in some groups of school children having an average diet, the incidence of chilblains compares favourably with others having an added amount of vitamins A and D, and it can be stated definitely that some apparently healthy children who have had a generous diet over a long period, containing more than a sufficiency of calcium, with additional amounts of vitamins A and D, may acquire chilblains on exposure to cold. It has also been noted that the incidence of chilblains in a group of London elementary school children (100) exposed to a carbon arc light during the winter was no less than in control groups.

CONCLUSIONS

In conclusion, I submit that the pathology of the chilblain is complex and still imperfectly understood. The actual lesion is not due to a mere transudation through the capillary wall, for the superficial vessels of the susceptible individual are the subject of a pathological change, which enables sudden lowering of the temperature to act with great intensity, destroying the endothelium of the peripheral vessels *en masse*. Among the predisposing causes are hereditary weakness, lowered resistance due to tuberculosis, and other toxaemias.

REMOVAL OF TONSILS AND ADENOIDS IN THE OUT-PATIENT DEPARTMENT

BY

J. ARNOLD JONES, O.B.E., M.B., F.R.C.S.ED.

SURGEON IN CHARGE, EAR, NOSE, AND THROAT DEPARTMENT, ROYAL MANCHESTER CHILDREN'S HOSPITAL; SURGEON, ST. JOHN'S EAR AND THROAT HOSPITAL, MANCHESTER

At the Annual Meeting of the British Medical Association held in Manchester in July, 1929, I opened a discussion in the Section of Diseases of Children on "Tonsils and adenoids: their medical and surgical aspects."[1] At the end of the meeting a resolution was passed by the Section condemning the operations for the removal of tonsils and adenoids in out-patient departments, and advocating a period in hospital, after the performance of such operations, of at least forty-eight hours. This was followed by much correspondence in the *British Medical Journal* vigorously supporting the resolution,

From my own experience of these operations, going back for a quarter of a century, my strong impression was that they could well be performed in the out-patient department, provided certain definite precautions were taken. It seemed to me unjustifiable to embark upon a large expenditure of money, which the treatment of such cases as in-patients would entail, unless more definite evidence of the need for reform was forthcoming, especially having regard to the present scarcity of money and the many infinitely more pressing needs that existed.

Among the impassioned opinions advanced by correspondents many dogmatic statements were made, but there was almost a total lack of real evidence one way or the other. Mr. E. Watson-Williams gave definite statistics in an article[2] to support his contentions, but the figures were not large, and the precautions taken omitted the most important one of sending the patients home in an ambulance.

In these circumstances Dr. Lapage and I suggested further inquiry, and I proposed that all surgeons interested should keep a careful record of cases for a year.

My record at the Royal Manchester Children's Hospital is here set down in tabular form. In drawing up the table I have followed the methods of Mr. Watson-Williams, whose record is placed below for comparison.

Table showing Number of Cases and Morbidity

	179 In-patients, August, 1929, to August, 1930		914 Out-patients, August, 1929, to August, 1930	
	Number	Per cent.	Number	Per cent.
Definite morbidity	0		7	0.7
Serious morbidity	3	1.6	5	0.5
Mortality	0		0	
Total morbidity	3	1.6	12	1.2

Mr. E. Watson-Williams's Table

	100 In-patients, March, 1918, to June, 1920	239 Out-patients 1919	
	Number	Number	Per cent.
Definite morbidity	1	7	2.9
Serious morbidity	0	3	1.3
Mortality	0	1	0.4
Total morbidity	1	11	4.6

The out-patient statistics have been very carefully compiled, every one of the 914 patients operated upon having been accounted for. This has involved a great deal of trouble, and I am deeply indebted to Dr. Fisher, Sister Macmurtry, and Miss Pilling (inspector N.S.P.C.C.) for their able and willing help. As many of the in-patients lived at a considerable distance away, the response to inquiry was meagre, not half of those operated upon being accounted for. The in-patient morbidity, therefore, may well be higher than indicated in the table. It will be observed that the percentage of total morbidity is higher among in-patients than out-patients, and that serious morbidity is three times as great. There was no mortality.

The precautions taken in the case of out-patients were as follows.

1. The cases were selected from, roughly, a five-mile radius of the hospital.
2. No "chest" or "heart" cases were included.
3. The older children were reserved for hospital.
4. No operations were performed if the weather was inclement—if east winds, fogs, or extreme cold prevailed. (During the period of this inquiry there were eight such occasions.)
5. The patients lay on couches in recovery rooms for three or four hours attended by a nurse.
6. They were examined by a medical officer before being sent home.
7. *They were sent home in the hospital ambulance.*
8. If the medical officer had any doubt about their condition, they were detained in hospital.
9. The parents were provided with printed directions as to after-treatment.

Mr. E. Watson-Williams, writing in the *British Medical Journal*,[3] says:

"Nine years ago you published my statistical evidence of the greater risks run by 'out-patient' *opérés*. . . . Despite the precautions advised by Mr. Arnold Jones—which, by the way, have long been universal practice—each year brought confirmatory evidence."

Now, to my mind, the most important precaution of all—namely, the sending home of patients in an ambulance, has not "long been universal practice." I have failed to find it mentioned by anyone; indeed, Mr. E. Watson-Williams implies in his paper[2] that after recovery from operation the patients are handed over to their parents, who are instructed on no account to let them walk. I cannot help thinking that if these patients had been sent home in an ambulance our figures might have more closely approximated.

These statistics, which cover only a single year with a mild winter, are but a contribution to a much larger inquiry; no final conclusions can be drawn from them. This much, however, can be said, that for one whole year these operations have been performed in the climatic conditions prevailing in the middle of one of the largest provincial towns (with the precautions previously referred to) and that the morbidity rate at the most has been no higher among out-patients than in-patients, and that the total rate has not been high.

CONCLUSION

As far as available *evidence* goes at present, apart from mere opinions based on impressions, I think it is fair to say that no case has yet been made out for insisting, or trying to insist, that these operations should not be performed upon out-patients. The alternative—that the authorities should provide the necessary bed accommodation for these cases—would entail a large expenditure of money, which would have to be found at the expense of other and more urgent surgical and medical needs.

With our present knowledge I am firmly convinced that, *with proper precautions*, the operation for removal of tonsils and adenoids can be performed on out-patients with as little risk as upon in-patients.

EPILEPSY AND PREGNANCY

BY

By J. A. STRUTHERS, M.D., M.R.C.P.

CASUALTY PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE WILLESDEN GENERAL HOSPITAL

The following cases are examples of a condition which appears to be sufficiently uncommon to merit notice.

Mrs. A. B. was seized with what was at first taken to be a series of very severe eclamptic convulsions starting ten days after the birth, at full term, of her first and only child (a stillborn male) in October, 1928. The description given by her husband was that she twitched all over and frothed at the mouth, and that she became unconscious and remained so almost continuously for four days, during which time there were frequent twitchings and convulsions, accompanied at times by the passage of urine and faeces. For the last month before delivery she had been confined to bed on account of albuminuria. Apart from this there was no history of previous illness; her husband also was healthy. Five months later, and again at intervals of seven and three months, she had further fits. During this time she had been treated with bromides. The omission of this drug shortly before she attended hospital in June, 1930, was followed by the occurrence of further fits, which were similar to the first, but not so severe, and lasting only a few minutes.

The only point of interest in the family history was that the father, who was still alive, had suffered from asthma as long as the patient could remember. Her mother and one brother were alive and well; the patient had never had any other brothers or sisters. There was no abnormality to record in the menstrual history. Physical examination failed to reveal any condition pointing to the presence of a cerebral tumour or other organic disease. Neither albumin nor sugar was detected in the urine. The blood pressure was 130/80. Wassermann and sigma reactions of the blood were negative.

In the second case, the patient was aged 28 when she had the first fit, in January, 1924. She was then six months pregnant with her first child. Whilst she was walking she had a sudden loss of power, preceded by numbness and accompanied by twitching in the left arm and leg. This lasted, she estimated, about three minutes, after which she was able to walk again. A few days later she had a "fit" during the night. On this occasion she "struggled violently," bit her tongue, was incontinent of urine, and later on suffered from a severe headache. During the remainder of the pregnancy the attacks of twitching and loss of power—always in the left leg and arm—increased in frequency up to three or four per day. The labour was normal, but fits continued afterwards with varying frequency. In June, 1926, just before admission to hospital, the frequency of the local fits was once every ten minutes of the day.

Examination in this case also failed to reveal evidence of organic disease. The cerebro-spinal fluid was normal, as also were the visual fields and retinae. The Wassermann and sigma reactions were negative. There was no history of any serious illness in either the patient or her family. During the subsequent four and a half years in which the patient has been watched and treated with bromides, fits have occurred from time to time, and have usually been left-sided.

The third case is similar. The patient in this instance was aged 26 when first seen, and had two children—a girl aged 2 years and 4 months, and a boy aged 7 months. During each pregnancy she had a single convulsion accompanied by unconsciousness, and without doubt, from the description of those who saw it, an epileptic attack. There was no past history of such attacks or of petit mal, but she had suffered from headache and severe symptoms of neurasthenia since an attack of "feverish illness" at the age of 18. There was a history of "concussion" at the age of 13. Physical examination when she was first seen in consultation proved negative, as also had previous examinations and exhaustive investigations, except that the uterus had been found to be retroverted. Throughout the following five months, during which she led a normal life, there were no attacks, but then she had a typical epileptic attack, followed during the next two months by several more, always occurring at night. She was almost unconscious of them, but in the morning she had recollections of a bad nightmare, which disturbed her considerably. The question of cerebral tumour was considered, but no evidence was found to support that diagnosis. There was one further attack in the following month, but during the seventeen months for which the case has been subsequently followed there have been no more attacks, in spite of the fact that no luminal or bromide has been administered in the last twelve months. Her general condition is that she is easily tired; and there are symptoms of intestinal dyspepsia. Menstruation has been irregular since it first commenced, the periods being often ten to fourteen days late and lasting six or seven days, but the loss appears to be normal and there is no dysmenorrhoea. The patient's mother has suffered from the severest form of migraine.

Similar examples previously recorded include those mentioned by Gowers,[1] who found ten in his series of 3,000 cases of epilepsy (52 per cent. females and 48 per cent. males) in which the onset was associated with pregnancy. In five of these cases the onset was before parturition and in five soon after. In one of the former group the attacks occurred during each of five successive pregnancies, but only during sleep. They then became constant, and occurred also during the day. Muskens[2] quotes the case of a woman who had her first epileptic fit, at the age of 32, in the sixth month of her first pregnancy; this caused a miscarriage. For some time afterwards she had attacks every four weeks, and later pregnancies were often accompanied by fits. After the climacteric she had epileptic fits and syncopal attacks. This patient's father suffered from severe headaches, and her sister was an epileptic. Toulouse and Marchand[3] mention two cases, out of a series of 350, in which the epileptic attacks started during pregnancy—in one at the third month of the first, and in the other at the fifth month of the third—and persisted thereafter. They also mention cases recorded by others in which the "epileptic attacks" ceased with the end of pregnancy. These included one of a woman who had eight children—five male and three female—in whom a pregnancy with a male child was accompanied by fits. In this type it seems at least probable that the attacks were eclamptic in nature. Aldren Turner[4] and Féré,[5] it is true, consider eclampsia to be an acute form of epilepsy, and present a large number of cases in support of their opinion. This raises further important questions, and if, as seems probable from the recent work of Theobald,[6] this proposition should be established, still further support will be given to Collier's[7] view that epilepsy should be classed as a metabolic dyscrasia.

I am indebted to Professor F. R. Fraser and Dr. Geoffrey Evans for permission to publish particulars of the second and third cases respectively, as these were under their care.

TREATMENT OF ADVANCED CASES OF INTESTINAL OBSTRUCTION OR STRANGULATION*

BY

D. C. CORRY, M.D., F.R.C.S.

ASSISTANT SURGEON, RADCLIFFE INFIRMARY

A clinician on being taken to see a case of acute intestinal obstruction inquires if regurgitant vomiting has commenced. For he knows that before regurgitant vomiting sets in the patient has a good chance of surviving, but that once it is established the prognosis is grave. By the time the vomit has become faecal the prognosis is bad.

Patients suffering from advanced intestinal obstruction are liable to die from known and appreciated risks, such as the inhalation of vomit during anaesthesia, or the perforation of a damaged bowel into the peritoneal cavity. But they are also liable to die suddenly and unexpectedly. To account for these unexplained deaths two theories have been put forward. The first is that death is caused by toxins, either chemical or bacterial, produced in the obstructed bowel. The second is that death is due to the loss of water and electrolytes from vomiting.[1] [2] It is chiefly the effects of the loss of water in an advanced case that I wish to discuss.

DEHYDRATION IN INTESTINAL OBSTRUCTION

The dehydration of intestinal obstruction is comparable to that seen in cholera, where water loss is universally acknowledged to be a contributory cause of death. Lawrence[3] has recently drawn attention to water loss as being the cause of non-recovery in diabetic coma.

In cholera the fluid is lost in the stool, in diabetes in the urine, and in intestinal obstruction in the vomit. The fluid loss from gastric secretion alone may reach six litres in twenty-four hours.[4]

In the dehydration of these three diseases the following conditions are common to them all. Lawrence drew attention to their presence in diabetic coma and in cholera, and called them the "dehydration complex."

1. Tissue depletion of fluid.
2. Low blood volume and pressure.
3. Scanty secretion of urine.
4. High blood urea.
5. Low blood chloride.

All these conditions of the dehydration complex are present in an advanced state of intestinal obstruction.

1. The tissue shortage of water can be seen by the dry tongue, the thirst, the dry skin, the shrunken features—hollowed eyes and low ocular tension.

2. The pulse is usually rapid, but always of a low tension and volume.

3. The decreased secretion of urine has been described[5] as one of the diagnostic features of small intestine obstruction. That anuria is an occasional symptom of intestinal obstruction was brought home to me by the following case.

A man, aged 35, was admitted to Ancoats Hospital, with a history of anuria for four days, vomiting, pain in the back. According to a blood urea estimation, done under the impression that it was a case of calculus, anuria was 250 +. The patient died that night, and necropsy revealed a volvulus of the small intestine. The kidneys appeared healthy.

In the oliguria of intestinal obstruction there is usually a trace of albumin, and in some cases renal casts and blood.

4. Tileston and Comfort,[6] in an investigation of the blood ureas in a series of diseases, found that in intestinal obstruction the blood urea was far higher than in any other disease, except those affecting the kidneys. The following case reported by Leslie Smith and Heritage[7] indicates the high level the blood urea may reach, and yet on recovery the kidneys may apparently be normal.

A man, aged 28, was admitted in a comatose condition to Ancoats Hospital. The history of his illness, obtained from his relatives, began five days previously with colicky pain round the umbilicus. His bowels had not opened for three days, and vomiting had occurred for the same period. On his admission the vomit was faeculent. The abdomen was distended, visible peristalsis being seen. Blood urea was 240. The urine was dark and showed a few casts. Later, cerebro-spinal fluid urea was 350. The comatose condition seemed so profound that death was considered imminent, and operative intervention useless. Improvement took place after intravenous saline had been given, and Mr. Hughes operated. The obstruction was caused by a band four feet above the ileo-caecal valve, division of which resulted in the patient's return to consciousness the following morning. Blood urea five days later was 40; fourteen days later, 21. The urine contained no albumin or casts.

The high blood urea observed when the patient has begun to vomit is not due to the failure of the kidney to excrete this, as the urine passed contains a high concentration of urea. It is due presumably to increased destruction of tissue protein. Later, when casts appear in the urine, there must be a definite nephritis (? toxic), and this is shown by the failure of the kidneys in renal dye tests.[8]

5. The decreased blood chloride of intestinal obstruction is especially stressed by Haden and Orr.[9] They endeavour to correlate the blood chloride findings with the prognosis. The normal limits of blood chloride may be taken as between 0.27 and 0.32. They consider that the prognosis becomes worse and worse in proportion to the fall of the blood chloride below 0.26. As treatment they advocate giving 500 c.cm. of 5 per cent. saline morning and evening. Exactly what causes the fall in the blood chloride is a matter for conjecture. Some chloride is lost in the vomit, yet Haden and Orr found that a fall of chlorides occurred in the experimentally obstructed rabbit, which does not vomit. Yet in the rabbit the lost chloride might well be in the dilated stomach and duodenum.

A clinical symptom in intestinal obstruction, which may be due to the fall of the blood chlorides, is the cramp that occurs in the calf muscles of some of these patients. Is this similar to the cramp of stokers who lose salt from sweating?

That death occurs earlier in high intestinal obstruction than in low obstruction can be ascribed partly to the earlier onset of vomiting in high obstruction and subsequent loss of fluid. In low obstruction of the ileum Wilkie[2] was able to show by animal experiment that the fluid secreted into the afferent bowel is re-absorbed by the bowel higher up. Similarly the lack of symptoms in colonic obstruction could be ascribed to the well-known powers of the colon in absorbing fluid.

From these observations I consider that the severe dehydration seen in intestinal obstruction shows all the points of the dehydration complex seen in cholera or severe diabetic coma.

TOXAEMIA OF INTESTINAL OBSTRUCTION

In regard to the toxaemia of intestinal obstruction, Whipple[10] isolated and obstructed a loop of dog's duodenum. An extract from the occluded loop, when injected intraperitoneally into another dog, caused it to die vomiting, with symptoms resembling intestinal obstruction. This toxin, which Whipple considered to be a proteose, could be heated to 70° C. without losing its efficacy.

A certain amount of evidence has been brought against this proteose toxin of Whipple. Magnus Alsleben[11] found

* A paper read to the Oxford Clinical Club.

normal duodenal secretion to have the same effect. In a series of experiments Wilkie[2] found the duodenal toxin to be harmless to normal intestinal mucosa. Williams[12] suggests that these proteose toxins are produced by heating the duodenal contents to 70° C., as was done by Whipple in their preparation. If prepared by filtration and centrifuging, they are non-toxic. I will not discuss at present whether the toxin is a bacterial one produced by *B. welchii*, but state that there is good experimental evidence to encourage the use of anti-gas serum.

TREATMENT

The above considerations have caused me since May, 1929, to treat my severe cases of intestinal obstruction by giving 2½ to 3½ pints of intravenous saline during operation, which is rather a larger quantity than is generally advocated in such cases. I have used normal saline, as it is convenient, and it seems to me that it is essentially fluids that these patients require. There might be something to be said in favour of 1.2 per cent. saline with traces of other salts as used by Rogers in treating cholera patients. The 5 per cent saline of Haden and Orr certainly gives them salt, but he gives them less than a pint of fluid at a time. In the intravenous saline I give *B. welchii* antitoxin.

The operations are done under local anaesthesia. On return to the ward a continuous rectal saline and glucose is given by the Murphy drip method at the rate of a pint an hour. A dehydrated case will absorb another three or five pints during the night. On return to the ward 20 units of *B. welchii* antitoxin are given intramuscularly, and morning and evening till the bowels open. I have been agreeably surprised at the general condition of these patients next day.

NOTES ON ADVANCED CASES

Case 1.—A female, aged 29, was seen on May 2nd, 1929, with a right inguinal hernia, which had been strangulated for seven days. The skin over the hernia was red and shiny. Faecal vomiting was present. Using novocain as a local anaesthetic I operated, and in incising the skin found pockets of pus in the subcutaneous fat, but no gas. (A culture of this pus grew *B. welchii*.) The sac contained 8 inches of gangrenous small intestine, which was removed by resection; thereafter lateral anastomosis was done, and the peritoneum was drained. Three pints of saline with 50 c.cm. of *B. welchii* antitoxin were given intravenously during the operation, at the rate of one pint every ten to fifteen minutes. A rectal saline of 50 c.cm. *B. welchii* antitoxin was given intramuscularly in the first twenty-four hours, and a similar dose during the second twenty-four hours, following operation. The patient was very fit the morning after operation, and the bowels were open on the third day. The wound was granulating satisfactorily eighteen days after the operation, when the patient, who had had previous mental treatment, became cataleptic, and was transferred to a mental institution.

Case 2.—On August 25th, 1929, a female, aged 70, was seen on account of a right femoral hernia, which had been strangulated for three days. Vomiting was regurgitant and faeculent. At the operation, which was performed under local novocain anaesthesia and by the method of inguinal approach, a loop of strangulated small intestine was found to be viable. During the operation three pints of normal saline and 40 c.cm. of *B. welchii* antitoxin were given. The after-treatment was carried out as described above. Recovery was uninterrupted.

Case 3.—On October 27th, 1929, I operated on a male, aged 56, who had had a strangulated right femoral hernia for five days, and who was suffering from faeculent vomiting. Spinal stovaine was used, and the operation was carried out by the method of inguinal approach. A strangulated knuckle of bowel was found; it was gangrenous along the line of constriction. Resection and lateral anastomosis was done; 2½ pints of intravenous saline were given during the operation, with 50 c.cm. *B. welchii* antitoxin. The after-treatment was carried out as described above, and recovery was uninterrupted.

Case 4.—On December 3rd, 1929, a female, aged 72, was seen by me on account of a right femoral hernia, which had been strangulated for three days. She was having regurgitant vomiting. Using the method of inguinal approach, and employing novocain locally, I operated, and found that the sac contained 4 inches of gangrenous small intestine; I resected 8 inches, and then did a lateral anastomosis. During the operation three pints of normal saline and 40 c.cm. anti-gas serum were given; the routine of after-treatment followed the usual lines. There was some suppuration in the subcutaneous tissues, which were incised on the tenth day. The recovery was otherwise uneventful.

Case 5.—A female, aged 66, suffering from a right femoral hernia which had been strangulated for two days, was operated on by me on June 16th, 1930. Novocain was used as a local anaesthetic, and I chose the method of inguinal approach. Prior to the operation the patient was suffering from regurgitant and faeculent vomiting, but I found that the small intestine, though strangulated, was viable. During the operation 3 to 3½ pints of normal saline and 40 c.cm. *B. welchii* antitoxin were given. The after-treatment was as described above, and recovery was uninterrupted.

SUMMARY

Attention is drawn to the dehydration of intestinal obstruction similar to that stressed by Lawrence in diabetic coma, and by Rogers in cholera. All three diseases show tissue shortage of water, high blood urea, low blood chlorides. Large quantities of intravenous saline (2½ to 3½ pints) associated with *B. welchii* antitoxin can be given advantageously during the operation for intestinal obstruction, followed by rectal saline and glucose after operation.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

SERUM ANAPHYLAXIS

In view of the widespread use of serum in the treatment of various diseases, the two following cases are of importance.

A boy, aged 16, suffering from pyaemia, was receiving, with other treatment, intravenous doses of antistreptococcal serum. He had six of these without any untoward effect. While receiving the seventh dose he suddenly began to cry out that he could not get his breath, and exhibited all the signs and symptoms of anaphylaxis. The previous dose of serum had been given only three days before, and the make of serum used was the same throughout.

The other case is that of a woman, aged 30, suffering from suspected puerperal septicaemia. She had six doses of serum, and while receiving the seventh dose she exhibited the classical signs of anaphylaxis. The previous dose of serum had been given only two days before, and the make of serum used was constant.

In each case the serum was being given intravenously, and the symptoms commenced before the needle had been withdrawn from the vein. Both patients responded very well to adrenaline, and recovered completely in a short time.

These cases are of great interest in that the interval between the two last doses of serum was three days in one case, and two days in the other. Every textbook leads one to believe that serum given in doses at intervals

of less than ten days is perfectly safe. Evidently this is not so. It would seem to be a wise precaution always to have adrenaline ready for administration in every case when serum is given.

Our thanks are due to Dr. H. H. MacWilliam for permission to publish these cases.

LABOUR AND MITRAL STENOSIS WITH INCOMPETENCE

Mitral stenosis, one of the graver of the chronic valvular lesions, is almost always accompanied by a degree of incompetence. That the strain of pregnancy and labour has an adverse effect on the prognosis of valvular disease is recognized. Fatal terminations are not unknown, but auricular fibrillation or tricuspid incompetence and progressive cardiac failure are more likely to supervene when the disease affects the mitral valve. The case here recorded illustrates an unusual complication arising during labour in a woman suffering from mitral stenosis.

Mrs. A., aged 35, had an attack of acute rheumatic fever when 9 years of age. There was no history of any other serious illness. Her four previous pregnancies and labours had been uneventful, and there had been no symptoms of cardiac insufficiency. This (her fifth) had also been normal. On September 7th, 1930, at 9 a.m., the first definite labour pains were noticed. The position was left occipito-anterior, pulse regular in time and force, rate 80 per minute. Cardiac dullness was increased, especially to the right, the right border being 2½ inches from the middle line. Auscultation revealed mitral stenosis and incompetence. On September 8th, at 12.30 a.m., the patient delivered herself of a healthy female child weighing 12¾ lb. Labour had therefore lasted fifteen and a half hours, the slight delay being due to the large child. The pulse had remained at 80 beats per minute until one hour before delivery, when it was last recorded. Just after delivery of the placenta, a few minutes following the birth of the child, the patient suddenly became blanched, but a few seconds later regained her normal good colour. Similar rapid alterations in colour were observed during the succeeding ten minutes, and at the same time there was considerable loss of blood, amounting to a haemorrhage. The pulse rate was 32 per minute, was regular in time, and of good force. With pressure on the fundus the bleeding was controlled and the patient looked better. An hour and a half later the pulse rate was 42 per minute, with a similar heart rate and regular rhythm. Twelve hours later heart and pulse were regular in rhythm, and their rates 40 beats per minute.

On September 9th the heart rate was 40 and the pulse rate 40; both regular. Respirations were 20 per minute. The patient was feeling well. On September 10th the heart and pulse rates were as above, but the respirations had increased from 20 to 64 per minute. The patient complained of slight cough, but otherwise felt very comfortable. On questioning, haemoptysis was stated to be present, and on examination there was dullness of the right apex, with increased vocal resonance and very faint breath sounds. A diagnosis of pulmonary infarction was made: The temperature throughout never rose higher than 99° on the fifth and again on the seventh day. On the fifth day mild auricular fibrillation set in. This was controlled with digitalis, and the patient's convalescence was thereafter uneventful. The area of infarction cleared up, and the patient was able to get up on the twenty-fourth day after confinement.

The chief points of interest are:

1. The physical strain and effort of a hard labour in a patient suffering from rheumatic infection of the heart precipitated an attack of heart-block of a severe degree. Although the onset was ushered in with alarming symptoms the attack proved to be temporary.

2. The infarction of the right apex, due most probably to a small intracardiac thrombus from the right auricle or ventricle. Most infarcts are found in the lower lobes.

3. The absence of marked symptoms pointing to infarction apart from the increased respiratory rate and slight cough. Haemoptysis had to be inquired for.

A FATAL CASE OF POISONING BY PHENYLCINCHONINIC ACID

Several fatal cases of poisoning by phenylcinchoninic acid have been recorded, and the following may therefore be of interest.

A man, aged 60, consulted me on account of feeling ill and being jaundiced. He had never had a severe illness, but had lived a large part of his life in the East, and had had malaria, though not badly. He was a moderate drinker.

His pulse was slow, his temperature was subnormal, and he presented a slight icteric tinge. The tongue was a little furred, and there was anorexia and nausea. The liver edge was just palpable.

On a diagnosis of catarrhal jaundice, I placed him on small doses of alkalis and the usual diet. Three days later he was worse; his tongue was very dirty, vomiting was very troublesome, and his stools were clay-coloured; the jaundice was much deeper. After much questioning, I discovered that he had been taking phenylcinchoninic acid (on the advice of a non-medical friend whom he had met in India two months before) for what he thought was gout. He had taken 45 grains a day for a maximum of four days; he then rested three days, and resumed. This had been going on continuously for the two and a half months preceding his illness.

Two days after this he became drowsy, his pulse rose, and I sent him to a nursing home. His stools were now normal in appearance. Van den Bergh's test gave a direct positive result, with forty units of bilirubin—about eighty times the normal amount—in the indirect reaction. Next day the jaundice was intense, the drowsiness increased, and his pulse was 100. His urine then contained albumin and the urea content was 1.65; no leucine or tyrosine crystals were seen, and it was strongly alkaline. Ehrlich's diazo reaction produced a reddish-brown coloration, and Schlesinger's test for urobilin was negative. The fair amount of urea, and the absence of leucine and tyrosine was then of good omen, but the clinical picture of intense toxic jaundice was very disquieting. At this time the left lobe of the liver, which had been enlarged, ceased to be palpable. There was no abdominal tenderness. Two days later he became comatose. I replaced two pints of his blood with normal saline solution, which roused him for a little while, but he relapsed and died twenty-four hours later.

The post-mortem examination revealed as follows: The body was well nourished, and there was a right inguinal hernia. The stomach and duodenum showed signs of a severe catarrhal condition of the mucous membrane, but there was no ulcer or growth. The pancreas seemed normal, but the spleen was enlarged, and there were yellowish patches over it. The liver was somewhat shrunken, soft, and friable, and covered with yellow areas of necrosis. The gall-bladder was normal, with no stone. Microscopical section of the liver showed intense cloudy swelling, with fragmentation and focal necrosis at the periphery of the lobules. Death was due to acute hepatitis, which in the absence of any other exciting cause must be attributed to the drug. The amount taken was not much in excess of that commonly prescribed, nor is the period over which it was taken exceedingly out of the way.

Possibly the chronic hepatitis attributed to those who have spent much time in the Tropics rendered his liver cells less resistant to the toxic action of the drug—supposing that it acts directly, and not by means of the gastro-duodenitis which it produces. The rapid progress of the case to a fatal issue is also perhaps noteworthy.

I am indebted to Dr. R. Waterhouse for his opinion and pathological work in this case.

British Medical Association

CLINICAL AND SCIENTIFIC PROCEEDINGS

CALCUTTA BRANCH

A clinical meeting of the Calcutta Branch was held on December 12th, 1930, in the lecture theatre of the School of Tropical Medicine and Hygiene, Calcutta, with Lieut.-Colonel V. B. GREEN-ARMYTAGE in the chair.

PATHOLOGY AND TREATMENT OF SPRUE

Lieut.-Colonel H. W. ACTON, I.M.S., in a paper on the pathology and treatment of sprue, pointed out that sprue was not a disease entity, but a syndrome occurring as an end-stage in dysenteric infection. The sprue syndrome had certain fairly constant features. It occurred as a rule in the Tropics or sub-Tropics; its manifestations were evidence of derangement of the gastro-intestinal tract; it was more common in Europeans than in Indians, and it was occasionally a house disease; there were also typical tongue symptoms and characteristic stools. The different guises under which the syndrome might appear clinically were next considered. (1) The so-called acholic diarrhoea; this was seen especially in children between the ages of 5 and 12 years. Tongue signs and symptoms were usually absent, anaemia might or might not be present, and the patient passed one or two large pasty stools in the twenty-four hours. A case seen by the lecturer presented an appearance similar to that of Hirschsprung's disease. (2) A certain proportion of cases labelled hill-diarrhoea were really manifestations of the sprue or pre-sprue syndrome. (3) The frank sprue case, with typical sore tongue, Addisonian-like anaemia, and gastric or intestinal lesions; this type of case was seen typically in adult Europeans, and was due, as the speaker subsequently pointed out, to streptococcal embolization. Owing to differences in digestive metabolism this type of case was not seen in the Indian, in whom asthenic diarrhoea was the prominent feature. (4) Cases with almost exclusively tongue symptoms—tropical aphthae so called.

In the course of a brief account of his bacteriological studies on the sprue syndrome Colonel Acton said that, during the early or pre-sprue state, bacilli of the dysentery group (Flexner, Shiga, Y, or Strong) were frequently detected in the stools. Atypical phage-mutants, such as *Bact. pseudo-carolinus*, giving aberrant biochemical and serological reactions, were also common. In the fully developed sprue stage the stool was large, pale, and acid in reaction. It contained numerous fatty-acid crystals, yeasts, and haemolytic non-lactose-fermenting streptococci, but no flagellate protozoa, and very seldom any typical members of the dysentery group. The invasion of the blood stream by these streptococci and the subsequent formation of bacterial emboli were, in the speaker's opinion, the essential causes of the signs and symptoms of well-developed sprue. Gas-forming aerobes were also frequently detected, and there appeared to be, in addition, a group of organisms capable of producing leucobases; plating on Sabouraud's medium revealed monilia in many cases. Radiological investigations indicated that bowel stasis was constantly present in well-marked cases. This stasis was due to the action of toxins on the muscle of the bowel wall, together with atony due to lack of absorption. It was manifested at three points—in the caecum, in the transverse colon, and in the descending colon.

Colonel Acton prefaced his remarks on treatment with a brief historical survey. Not so many years ago the only treatment known was to send the patient home for a prolonged holiday—essentially a counsel of despair. Yellow santonin and streptococcic vaccines each had their day, to be followed in turn by the strawberry cure, treatment by calcium and parathyroid extract, liver extract, and ventriculin treatment, and finally by bacteriophage. In the speaker's opinion residence in hospital was essential for the successful treatment of a well-developed case of sprue. Carbohydrates should be cut out of the diet, which in the early stage should consist mainly of soups and eggs. An exclusively milk diet was unsuitable, as patients rapidly become nauseated. Bacteriophage treatment had, as a rule, given disappointing results in the lecturer's hands. Autogenous vaccines are successful in certain cases; where anaemia was marked, liver extract, about 7 oz. per diem, was useful. Transfusion was, on the whole, contraindicated, except to hasten convalescence; certain cases did well under parathyroid and calcium therapy. In gastric cases ventriculin appeared to be markedly beneficial, and optochin was indicated as a local treatment in cases with marked tongue lesions.

In the discussion which followed, the CHAIRMAN dealt briefly with his experience of the sprue syndrome as it affected the course of pregnancy. In the last year he had seen five cases of sprue complicated by pregnancy; on delivery all the infants showed bony deformities, and this, in his opinion, was more than a coincidence. Dr. SHAHA said that he had had good results in one case on a milk regime. Dr. GUPTA referred to the marked wasting and the megaloblastic changes seen in sprue. Dr. COLTMAN expressed the opinion that fats caused a definite increase in the diarrhoeic symptoms. He thought that many of the cases of so-called coeliac disease seen in children in England were really examples of the sprue syndrome. Colonel KIRWAN suggested that many inflammatory conditions of the eye (keratitis, cyclitis, iriditis, and choroiditis) were really due to intestinal infections, despite the fact that bacteriological examination of the stool was very often inconclusive.

HYDATIDIFORM MOLE

The CHAIRMAN (Colonel Green-Armytage) showed a small series of specimens of gynaecological interest. The most remarkable of these (demonstrated by permission of Dr. Subodh Mitra) was a perfect example of chorion-epithelioma following on a hydatidiform mole in which the corpus luteum cysts were beautifully demonstrated. In his remarks on the treatment of this condition the Chairman emphasized that modern gynaecological opinion on the Continent and in England coincided in the view that the diagnosis of hydatidiform mole should be followed by immediate hysterotomy, and if the wall of the uterus was invaded, by hysterectomy. This dictum was based on the observation that no fewer than 18 per cent. of all cases of hydatidiform mole became malignant and a further 36 per cent. died of sepsis. Colonel Green-Armytage then dealt briefly with the important work of Zondek and Aschheim in Germany and of Evans and Simpson in England, on the formation of corpus luteum cysts. He urged the necessity for a more extensive use of the Zondek-Aschheim test, particularly as an aid to the diagnosis of hydatidiform mole and in the differential diagnosis of ectopic pregnancy from ovarian cyst.

Reports of Societies

SUGAR IN THE DIET OF THE SCHOOL CHILD

A meeting of the Section of Odontology of the Royal Society of Medicine was held on January 26th, with Mr. CARL SCHELLING in the chair.

Mr. J. E. CURNOCK read a memorandum on a cyst of unusual size which had involved the whole of one mandible, from the symphysis to the ascending ramus, and had obliterated the sigmoid notch. The patient had been edentulous for fourteen years before the appearance of the cyst, which contained no tooth and was not multilocular. The whole of the right half of the jaw was removed by Mr. Norman C. Lake, and the patient did well, but unfortunately died from melanotic sarcoma some months later.

Mr. G. T. HANKEY described a case of replantation of the upper central incisors of a schoolboy, aged 13; the operation had been unsuccessful owing to rapid absorption of both roots. The paper was discussed by Mr. J. G. TURNER, Mr. H. H. KENSHOLL, and Mr. G. C. FRIEND, and it was agreed that an organism responsible

for a chronic low-grade sepsis must have been introduced when the teeth were replanted.

Dr. A. A. OSMAN read a paper on the importance of sugar in the diet of the school child. The predilection on the part of children for sugary foodstuffs, he said, probably indicated a physiological need. Members of the dental profession were responsible for the campaign against the giving of sugar and sweets to children because of the possibility of injury to the teeth, but it was likely that some children, in consequence, suffered from a relative sugar starvation. The activity of the child and his enormous energy output made a readily assimilable and combustible form of fuel necessary. Immediate needs were best met by monosaccharides and disaccharides, the use of the polysaccharides, such as the starches, being to replenish at leisure. The science of dietetics was at present in its infancy, and Pembrey's dictum should be recalled: "Instinct is a good guide, and is in advance of the knowledge current at any time." The major symptoms of sugar deprivation included cyclical vomiting, or so-called bilious attacks; convulsions or other symptoms comparable to those produced by an overdose of insulin were fortunately rare. Cyclical vomiting usually occurred in the "nervous child"; the exciting factors were mental fatigue and excitement, infection, and physical exhaustion. In the majority of cases it was possible to prevent such attacks altogether if sufficient sugar were added to the diet. The minor symptoms of sugar deprivation could be summed up in the word "fatigue." The child was pale, tired, drooping, listless, and was brought to hospital for anaemia, headaches, flabbiness, fainting attacks, constipation, "growing pains," or asthma. In many cases these symptoms had been aggravated by the giving of extra milk. From a considerable experience he had no hesitation in saying that an insufficient utilization of sugar, either actually or in relation to the amount of fat consumed, was the most common cause of most of these symptoms, and in a majority of cases they cleared up on increasing the allowance of sugar in the diet. Much had been written of acidosis in relation to cyclical vomiting. Acidosis might be defined as decrease in the normal alkali reserve of the blood, however produced; a true acid intoxication rarely occurred. Ketosis arose when, owing to imperfect oxidation of fats, the ketone bodies, oxybutyric acid, diacetic acid, and acetone were formed, and was the condition found at the height of an attack of cyclical vomiting. But in the majority of cases of "debility" in children there was no ketosis, though there was diminution of the alkali reserve. Neither ketosis nor hypoglycaemia was a constant finding in these subnormal children, but when the sugar in the diet was increased it was generally found that the acidosis disappeared. Sugar could be given with advantage in the form of glucose, because it could be prescribed as a medicine. Lemonade or tea containing two or three teaspoonfuls of sugar to each cup, bread-and-butter sandwiches of Demarara sugar, plenty of syrup, honey and jam, and boiled sweets, could be given with success. It was advisable to limit fat and milk somewhat.

Mr. F. W. BRODERICK expressed the opinion that the main cause of dental caries was acidosis; there was no fear that caries would be increased by giving sugar—in fact, the opposite was to be expected. Mr. W. A. BULLEID shared Dr. Osman's view. It was inconceivable that pure sugar, which was highly soluble, could remain long in contact with the teeth under the steady flow of saliva. Moreover, he had found that the child who was always sick with excitement at parties could be cured of his disability by a prophylactic dose of barley sugar the night before.

Dr. KINGSTON BARTON thought that sugar should not be given to the child in the form of accessory sweets, but should be included in the diet, and Dr. R. P. GARROW asked what was implied by the phrase "extra milk," as used by Dr. Osman. Mr. A. T. PITTS agreed with Dr. Kingston Barton that the sugar should not be given to the child as sweets, which might be eaten at all hours of the day, and were particularly harmful if taken at bedtime. Mr. R. C. RIX referred to the recent work on the ketogenic diet used to control epilepsy, and asked whether Dr. Osman had ever observed the converse—namely, the development of fits in children previously free from them, on increasing the sugar in the diet. Dr. E. W. FISH said that probably some underlying factor determined the development of dental caries. Fermentable carbohydrate was present in everyone's diet, but some developed caries while others did not. A tendency to caries was hereditary, and the lesions always appeared at contact points, in permeable faults in the enamel. Where there was a permeable fault the tooth would sooner or later rot, and though caries was aided and abetted by sugar it would only mean that it occurred in these school holidays instead of next—not a very serious matter. Mr. J. G. TURNER referred to the possibility of debility in children being due to nasal sinusitis and its complications.

In replying, Dr. OSMAN said that by extra milk he meant the glass given at 11 o'clock in the morning at some schools; the average child could deal with it, but children of the type he described could not, unless it was balanced by a sufficient quantity of sugar. He had seen two cases in which apparent attacks of epilepsy had arisen following an increase of sugar diet, but among several thousands of children this represented a very small incidence, though it was a point to bear in mind.

ALKALI TREATMENT OF NEPHRITIS

At a meeting of the Aberdeen Medico-Chirurgical Society held on January 15th, with the president, Dr. HENRY PETERKIN, in the chair, Dr. W. F. CROLL described the course of a case of mixed nephritis, in which, he said, the main interest lay in the excellent diuretic response to the administration of alkali.

The patient, an unmarried woman, aged 42, was admitted to his wards on June 17th, 1930. She complained of backache, swelling of the face, trunk, and limbs, and of scantiness of urine. The symptoms commenced with swelling of the lower eyelids six weeks prior to admission. Headaches had been troublesome, and she also complained of shortness of breath, slight nose bleeding, and blurring of the vision. The family history was excellent, and the patient had no previous illness, apart from what she described as abscesses of the legs three weeks before the onset of the present complaint, lesions which might have been of some etiological significance. On admission there was marked pallor and great oedema of the whole body. The pulse rate was 92, respiratory rate 22, temperature 98.6° F., blood pressure 110/80, blood urea 32 mg. per cent., urea concentration 1.9 per cent. The urine was cloudy, acid, with specific gravity 1011 to 1022, and contained 0.7 per cent. of albumin and only a trace of chloride. The centrifuge deposit contained casts, pus cells, and a few red blood cells. The eye grounds showed no evidence of renal or vascular disease.

The patient was put on a milk diet. She grew rapidly worse, and for a few days was critically ill. The oedema increased, and it looked as if she were to be drowned in her own fluid. The conjunctivae even showed marked oedema. The amount of urine passed during the first week was 84 ounces. One week after admission an Epstein diet was prescribed, consisting of fish, lean meat, lean ham, white of egg, lentils, oysters, peas, rice, oatmeal, bananas. Fluids were restricted to two pints, and salt was excluded. Almost immediately there was a decided improvement. The daily volume of urine increased and the oedema

diminished. Three weeks later urea was given (15 grams thrice daily) as a further stimulant to diuresis, but, having no effect, it was discontinued. Six injections of novasurol were then given at intervals of three or four days, but there was no marked response. Nephritin was tried next in a dosage of two tablets four times daily. There was at first an increase in the urinary output, but this was followed by a decided fall, which more than counterbalanced the initial increase. Furthermore, the amount of albumin passed was greater. It was then decided to try the effect of alkali administration, as advocated by Osman.

Dr. Croll said that some decrease in the plasma bicarbonate appeared to be the rule in all cases of chronic nephritis, and that Osman recommended the administration of alkali in the form of equal parts of potassium citrate and sodium bicarbonate by mouth, in amounts sufficient to maintain the plasma bicarbonate at normal level. The carbon dioxide combining power of the plasma in the present case was 42 volumes per cent., a value somewhat below normal. The dose of alkali given was actually much smaller than that used by Osman. At first the patient took 50 grains of alkali thrice daily, and four days later the dose was doubled. The response could be described as dramatic. The volume of urine increased, and in six weeks the body weight was reduced from 161 to 108 pounds, and the patient was now well and active. Dr. Croll said that the mode of action of the alkali was somewhat obscure, but that, according to Fischer, the colloid proteins of the body cells had the property of absorbing or parting with water in response to alterations in the reaction of the surrounding medium. In nephritis there was a move to the acid side and a reduction of the plasma bicarbonate owing to the retention of phosphates. Fischer regarded the oliguria and albuminuria as being directly due to the swelling or oedema of the kidney cells. The oedema of the tissues he considered to be due to the associated acidosis, occurring independently of the renal lesion.

In the discussion that followed this paper Sir ASHLEY MACKINTOSH said that he had found great value in the use of urea as a diuretic in cases of this type.

Dr. J. ROSS MACKENZIE delivered an address on the convulsions occurring during surgical anaesthesia, and Sir JOHN MARNOCH described the history and appearance of a case of traumatic aneurysm of the plantar artery.

The annual general meeting of the Royal Microscopical Society for the election of officers and council was held at B.M.A. House, Tavistock Square, on January 21st, when Professor R. RUGGLES GATES was re-elected president. In his presidential address, after reviewing certain aspects of the history of the society showing its importance in the development of biology, and citing some of the eminent scientific men who had taken part in its work, Professor Gates discussed adaptations in cell structure. He cited various cases of complicated structures in the protozoa, and referred to the widespread occurrence of cilia in many animal and plant cells. The mechanism of mitosis or nuclear division was treated as an adaptive mechanism which originated very early in evolution, and had made possible the multicellular structure of higher organisms, at the same time serving to perpetuate many of the differences arising through variation. The capillitium in Mycetozoa and puffballs, the elaters of liverworts and of Equisetum, were discussed as examples of evolutionary adaptation, arriving at the same goal by different paths. The development of the spiral markings in wood cells was explained, and the long coiled suspensors of conifer embryos were treated as a study in adaptation and over-specialization through competition between the young embryos and the principle of developmental selection. The frequency of parallel mutations in the evolutionary development of many cell structures was emphasized, and it was shown that the principles of adaptation in cell structures were the same as in the development of adaptations in the organism as a whole.

Reviews

DEEP *X*-RAY THERAPY IN CANCER

The report entitled *Deep X-Ray Therapy in Malignant Disease*[1] is, as the author, Dr. WALTER M. LEVITT, states in his preface, a detailed account of an investigation carried out in the radiotherapeutic research department of St. Bartholomew's Hospital, under the direction of the hospital's Cancer Research Committee. The investigation covers a period of five years and deals with the treatment of malignant disease, in some cases by deep *x*-ray therapy alone and in others by a combined *x*-ray and radium therapy. The cases were chosen by members of the staff of the hospital, and after consultation with the radiologist; no case was admitted for *x*-ray treatment in the radiotherapeutic research department if there was evidence that the disease had become generalized.

The cases were restricted at first to four groups, but at a later date two more groups were added. These groups were as follows: malignant disease of (1) breast, (2) uterus, (3) upper air passages, (4) oesophagus, (5) rectum, and (6) thyroid. The term "malignant disease" included "any new growth which proved on microscopical examination to be a malignant tumour." The apparatus used is described in detail, as is also the technique employed in the treatment of cases in the various groups. The changes in these, which of necessity took place in five years, are noted; but, briefly stated, the cases were treated by *x* rays produced by a constant high-tension current of 185 to 196 kilovolts. The biological unit skin dose (U.S.D.) was adopted, this being defined as

> "that dose of *x* rays which, when applied in one sitting lasting from half to one hour, to the normal abdominal skin of a healthy adult, with a port of entry of 64 sq. cm., will produce a bright red erythema without vesication after an interval of twenty-one days, followed by pigmentation and desquamation."

To determine this dose in terms of a physical unit the Friedrich "e" unit was used; the dose as estimated in physical units, necessary to produce the U.S.D., varied from 123e to 220e, in accordance with the current used and the filtration employed. Here we may remark, parenthetically, that it seems rather a pity, as time went on, not to have adopted the "r" unit, which is now the recognized international standard of dosage. After a trial of the intensive single dose technique, which had already been discarded by the majority of radiologists, the divided or split dose technique was adopted. The interval between the doses was fixed at twenty-four hours. In practice, the number of fractions into which the dose was divided varied from 6 to 15. The duration of treatment was determined by the rate of growth of the tumour.

Other sections describe the management of cases during and after treatment, and the constitutional effects of treatment. Section V gives the results; and these are fairly and honestly stated. The breast cases, 43 in number, were all inoperable. Of these patients 20 died within the first year after treatment; but in November, 1929, 6 were alive and apparently free from the disease. Varying degrees of improvement were noted in 18 patients, several being able to perform a moderate amount of work for over a year. Considering the nature of the cases treated, the results were as good as anyone could reasonably expect. The "uterus group" comprised 60 cases, of which 48 were cancer of the cervix and 9 were cancer of the body of the uterus. The great majority of the cases treated showed some improvement, and 26 for

[1] *Deep X-Ray Therapy in Malignant Disease.* By Walter M. Levitt, M.B., D.M.R.E. With an introduction by Sir Thomas Horder, Bt., M.D. London: J. Murray. 1930. (Pp. xiv + 128; 10 figures. 10s. 6d. net.)

a time became "completely free from evidence of the disease." Of the patients treated, 26 are dead, 21 alive but with signs of the disease, and 13 alive with no evidence of growth present. The number of cases treated is of course too small, and the time that has elapsed too short, for a comparison of the results with those of other workers in this field. The most important group of cases, in point of numbers and originality of technique, was the "upper air passages." Of 170 cases, 141 were cancer, and in nearly all the cases the diagnosis was confirmed histologically; 27 of these patients are alive, "with no evidence of growth present." The method of treatment appears to be an excellent one, deserving an extended trial. So far as the rectal, oesophageal, and thyroid groups are concerned, the numbers are small and nothing new is to be recorded.

The report is a straightforward account of a limited number of cases of malignant disease treated mainly by "deep x rays." The author does not attach much importance to the "blood count," stating that "no prognostic significance can be attached to the blood counts"; this is a subject upon which little work has been done, but recent research work shows that the haematologist can furnish us with much valuable information which aids both in prognosis and in diagnosis. The conclusions are fair and not overdrawn. A useful index is provided. This report will not only be of value to the radiologist, but will also serve as a textbook on deep x-ray therapy for those who are studying with a view to a diploma in radiology.

FRANCIS GALTON

The first 137 pages of the third volume of *The Life, Letters and Labours of Francis Galton*[1] are devoted to the origin and growth of the calculus of correlations, with special reference to its application to the study of inheritance. The next 80 pages describe Galton's work on personal identification. The remaining 222 pages describe the last decade of Galton's life, which he dedicated to watching over, nourishing, and protecting his favourite intellectual child, eugenics. This volume includes many letters, but a further collection of more intimate personal letters forms a slimmer companion volume. In the preface, Professor KARL PEARSON anticipates criticisms of the scale of his undertaking.

> I have written my account because I loved my friend, and had sufficient knowledge to understand his aims and the meaning of his life for the science of the future. I have had to give up much of my time during the past twenty years to labour which lay outside my proper field, and that very fact induced me from the start to say, that if I spend my heritage in writing a biography it shall be done to satisfy myself and without regard to traditional standards, to the needs of publishers or to the tastes of the reading public. I will paint my portrait of a size and colouring to please myself, and disregard at each stage circulation, sale, or profit. Biography is thankless work, but at least one can get delight in writing it, if one writes exactly as one chooses and without regard to the outside world!

The apologia is disarming, and certainly in the matter of mere length none is needed, for every year almost as voluminous biographies are compiled of soldiers and politicians whose names will have been forgotten when the work of the great man here commemorated is familiar to all educated persons. Perhaps the plan, rather than the extent of the work, *is* open to objection from the point of view of literary art. The greatest biographical artists, such as Boswell and Sir George Trevelyan, have so used their material that the personality of their subject is always in focus; his writings have only been introduced with the object of throwing light upon his personality.

Professor Pearson has provided a complete exposition of, and commentary upon, nearly all Galton's scientific publications. The first two chapters of the present volume, for instance, might have been published with very little alteration as separate monographs upon the development of the theory and practice of statistical correlation, and upon the scientific use of finger prints as means of identification and classification. The general reader who, without being either very ignorant or very dull, finds some of the technical description hard to follow, will be apt to lose sight of Galton in his work; a result of which Galton himself would have heartily approved, but which is not conducive to literary satisfaction. But Professor Pearson, although (his prefatory disclaimer notwithstanding) a considerable literary artist, did not set out to produce a mere work of art, but a record of great scientific achievement, and, both in the body of the work and in the appendix of letters, has provided ample materials from which another great writer, less interested than Professor Pearson in Galton the man of science, and as interested as Professor Pearson in Galton the lovable human being, can prepare a more impressionist picture. Even if no such artist appears, the most casual of readers of these volumes can reconstruct a sufficiently delightful personality. Galton is revealed to us both as a lovable human being and as an amateur of science, an amateur not in the disparaging sense usually now attaching to the word, but in the sense in which the Greeks were amateurs—that is, men interested in all things and inspired with the faith that man's reason can solve all problems. No doubt the scientific thinker of 2,000 years ago needed a higher courage to adopt that position than a son of the nineteenth century, but at least the Greeks did not have to overcome the fear of being despised by "professionals."

Galton had a harder task than his cousin, for, after all, Charles Darwin did make himself "respectable" in the eyes of professional men of science by his specialist labours on barnacles before he attempted to shake their prejudices. Galton's courage led him into a field beset with mathematical difficulties, and his genius enabled him to accomplish more there than any properly accredited specialists. Professor Pearson gives many illustrations of the way in which Galton, already past the ordinary prime of life, and using quite simple mathematical tools, reached good approximations to the solutions of problems of a horrifying complexity. Small blame to the old hero if at times he was a little impatient of mathematical refinements. But "old hero" is an incorrect phrase; Galton never was old, he retained to the end the courage and enthusiasm of a boy and a boy's faith in the triumph of reason. It was so clear to him that eugenics must be the way of social salvation, that he never doubted that faith would triumph. Perhaps this indicates a necessary defect of his qualities; a lack of sympathy with unreason which is not the same thing as stupidity. On page 115 of this volume there is an interesting example in a comment on Wordsworth. It is clear that although Galton, a pioneer in so many fields, also anticipated modern students of the unconscious, he would have had but little sympathy with their point of view. But in his relation to individuals Galton was a man endowed with the most exquisite tact and power of sympathetic appreciation. The relation between him and his two greatest disciples, W. F. R. Weldon and his biographer, displayed in the letters which are the most charming part of this biography, is as touching as anything in the history of human friendships. The relations of Johannes Müller to du Bois Reymond and Helmholtz

[1] *The Life, Letters and Labours of Francis Galton.* By Karl Pearson. Vols. iii(*a*) and iii(*b*). London: Cambridge University Press. 1930. (Pp. xii + 673; illustrated. 69s. net the two volumes.)

and of Helmholtz himself to Hertz were similar. The octogenarian Galton retained the spirit of a boy, but it was mellowed with the wisdom of a man worldly-wise in the best sense of the term. One can easily understand how deep an affection he inspired.

INTESTINAL TUBERCULOSIS

Dr. LAWRASON BROWN and Mr. HOMER SAMPSON are to be congratulated on the pioneer work they have done on the *x*-ray diagnosis and the treatment of tuberculous ulceration of the intestine, of which they give a full account in the second edition of their book *Intestinal Tuberculosis*.[3] It is very valuable work indeed, and all those who treat pulmonary tuberculosis must make themselves acquainted with it. The reviewer's duty is presumably to tell his readers what the book under discussion is like as a book rather than to criticize in detail the subject-matter. And so in this case he must say that *Intestinal Tuberculosis*, as a book, is unworthy of the fine work which prompted the authors to write it. All the information is there, but it is a tedious task extracting it. The book has no crispness. For instance, the authors have made an exhaustive study of all the modern literature on the subject, and as leading experts they could have given an authoritative and critical digest thereof instead of a bewildering welter of other people's opinions and findings. Their own results, too, are obscured by endless pseudo-statistics on the "percentage" system which, in nearly every instance, could have been replaced with advantage by unsupported authoritative statements. But awkward though the book is, their work on intestinal tuberculosis is so good that with a sigh of resignation the interested physician will have to sit himself down and tackle it.

TREATMENT OF SYPHILIS

Professor A. SÉZARY claims that his book on the Treatment of Syphilis[4] has been written primarily for the student, but it should find more favour with the practising syphilologist, for it contains nearly all the information necessary for the treatment of syphilis in all its stages. The various remedies are reviewed, together with the indications for them—their doses, actions, accidents, and contraindications. The author divides his treatment, especially of primary and secondary syphilis, into two parts: the "attack," which lasts a year, and "consolidation," which extends over a period of three years. This is essentially in agreement with British practice, and is eminently sound, as also is his plan of giving arsenobenzene and bismuth concurrently rather than one following the other. A particularly good section is that on "Faults to avoid," including among others the danger of commencing treatment without being absolutely certain of the diagnosis, waiting too long before commencing treatment, giving too small doses of the drug or spacing them too widely, employing only one remedy at a time when one might use two (for example, arsenobenzene and bismuth or mercury), omitting the "consolidation" treatment, or neglecting signs of intolerance. In an excellent chapter on preventive treatment the author very wisely recommends that if more than fifteen days have elapsed after probable infection one should wait and watch before commencing treatment.

Omissions are few, but more space might have been allotted to jaundice and exfoliative dermatitis, two of the syphilologist's greatest causes of worry. More importance might have been accorded to the use of potassium iodide, and further explanation of the use—and abuse—of the Wassermann reaction and its interpretation, but these are small faults in an admirable little book. Many very sound pieces of advice and information are included—such as the best times to examine the cerebro-spinal fluid, the necessity of doing a Wassermann test before commencing treatment, how a Wassermann reaction may wobble between positive and negative at short intervals, and the wisdom of avoiding excess of alcohol and tobacco. Congenital syphilis is extremely well dealt with, especially the treatment of the potential mother, and this section brings to an end a book which can confidently be recommended.

DIET IN DIABETES

Dr. SANSUM has been one of the most insistent teachers of the necessity for making the diabetic diet approximate, by the aid of insulin, as nearly as possible to a normal diet. The monograph, of which he is joint author, on *The Treatment of Diabetes Mellitus with Higher Carbohydrate Diets*[5] is not a plea for administering higher proportions of carbohydrate than normal, but only a timely protest against the prevalent notion that diabetics are benefited by taking undue proportions of fat and protein in their diet. Sansum observes that, on the contrary, diabetics suffer many disadvantages from the excess of fat and protein to which they are still too often condemned. Insulin enables the diabetic to live on a diet which contains the same proportion of carbohydrate to fats and protein as the healthy person might take. This book will help the practitioner to choose and balance the diets of his diabetic patients so that they will enjoy the variety and profit immensely by the sensible amounts of carbohydrate which are permitted. It is a sound and readable little volume.

THE ANIMAL MIND

To those who, approximately thirty years ago, found inspiration and delight in the books of Professor C. LLOYD MORGAN in the realm of the then infant science of comparative psychology, the publication of his latest volume, entitled *The Animal Mind*,[6] will be very welcome; and to those who have entered the world since the issue of *Animal Life and Intelligence* in 1890, *Habit and Instinct* in 1896, and *Animal Behaviour* in 1900—whether or no they have read those books in the libraries in which they may still be found—this new volume should prove equally delightful and stimulating. The works named are now out of print, and others by the same author in kindred fields need some revision in the light of fast-developing knowledge and ideas. So, instead of issuing new editions, Professor Lloyd Morgan has taken much of the material of these books, and has completely reset it in this sequel, which may be said to "take up the running" by presenting it in new form after the work of a generation, which has to-day resulted in a different attitude towards biology, evolution, and psychology alike. The book is full of interest for the whole body of "gentle readers" to whom it is addressed, and is an entirely admirable example of clear definition of terms, of logical exposition, and of true and exact scientific method. Of course, it exemplifies its author's views and beliefs as to "emergent evolution," and as to the

parallelism of body-story and mind-story within the story of the organism as a whole; but where he strays, very properly and attractively, from science into philosophy, Professor Morgan is always careful to draw attention to the fact that he has done so. The book is, indeed, a masterly interpretation of observed animal behaviour, whether anecdotal or experimental, on a scientific as opposed to a dramatic basis. It is very interesting reading, and the results of the argument and the method by which they are arrived at should prove truly educational to the non-expert reader for whom the volume is intended.

NOTES ON BOOKS

Dr. LAEMMER, the author of a practical little work on diathermy in diseases of the alimentary tract,[7] claims that the use of diathermy in this field has a value which is only just beginning to be realized. For example, he has found it capable of relieving functional spasm of the oesophagus, mild gastritis, persistent vomiting, the pain of gastric and duodenal ulcer, colitis, constipation, and diarrhoea, as well as post-operative peritoneal adhesions. Diathermy has also been used with success in cases of hepatic insufficiency, painful congestion of the liver and in early stages of cirrhosis, in certain cases of gall-stones, and in chronic cholecystitis. Dr. Laemmer gives precise instructions for the administration of diathermy, and has suggested a method of treatment which is likely to give at least symptomatic relief in a number of affections where it is often badly wanted and difficult to procure by other therapeutic measures.

In *The Mystery and Lore of Monsters*,[8] with accounts of some giants, dwarfs, and pygmies, Mr. C. J. S. THOMPSON enters on a vast field, which his extensive and peculiar knowledge has furnished with many strange instances and some familiar ones. His is not a pathological or teratological study, but rather a record of what has been observed, or at least believed, about "the anthropophagi and men whose heads do grow beneath their shoulders." He gives reproductions of old cuts purporting to show these and other malformations and monstrosities, not forgetting the great sea serpent, whose appearances have become more and more rare *pari passu* with the retreat of the whale towards the South Pole. The records of giants, dwarfs, and prodigies who have been shown for gain is a long and sad one. We agree with Mr. Thompson that the exhibition for gain of human monsters should be forbidden, and the unfortunate subjects sheltered by the State. But the desire to see and wonder at such beings is deep-seated. When Stephano, in *The Tempest*, discovered Caliban and Trinculo, and took them for a monster of the isle with four legs, his first thought was to "recover him and keep him tame" and sell him for a show. The first part of this book is devoted to monsters, many of which are purely imaginary, such as the "Monster of Horrible Aspect" of Lycosthenes of 1557, but including attached twins and embryos. In the second part, on giants, dwarfs, and prodigies, we come nearer to actuality, for there are skeletons of a number of those described by Mr. Thompson in the Museum of the Royal College of Surgeons. From these and from such records as can be trusted it seems that the limits of adult length lie between two and eight feet. Caroline Crachiami, whose skeleton stands by that of Byrne O'Brien in the Hunterian Museum, was only nine years old when she died, so that her case is excluded. Whether any giant has exceeded eight feet seems doubtful. The skeleton of O'Brien measures 7 feet 8¾ inches, so that allowing for the soft parts his body cannot have exceeded 8 feet. We have come to the conclusion, after a study of this book, that it is better to be a dwarf than a giant, and that the middle height is preferable to both. According to the showman in *The Old Curiosity Shop*, the last years of giants are miserable. They go groggy at the knees, and, secluded from public view in caravans, are condemned to wait upon the dwarfs, most of whom are bad tempered.

Dr. FRANCIS BACH'S recent Chadwick Lecture on *Rheumatism: Its Significance in Youth and Middle Age*,[9] is now published in pamphlet form, together with part of a paper entitled "On acute rheumatism as a manifestation of rheumatic fever," read at the International Congress on the Rheumatic Diseases, held at Liège.

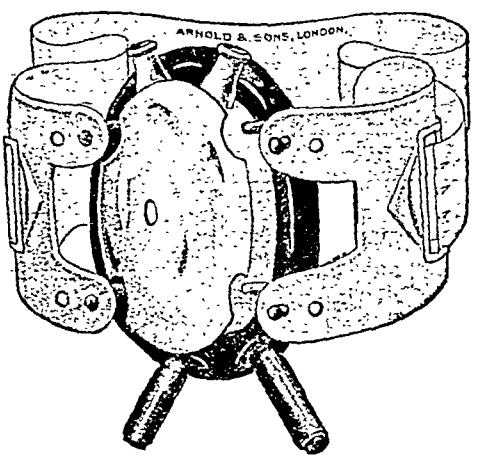
PREPARATIONS AND APPLIANCES

PADS FOR SUPRAPUBIC BOX

Mr. FRANK HARVEY, F.R.C.S. (London, W.1), writes: Messrs. John Bell and Croyden (Arnold and Sons) have made at my suggestion a modification of the rubber pads which I introduced about three years ago to fit the Hamilton-Irvine



suprapubic box. These pads are made of sponge rubber, with a plain rubber flange that fits over the lower projecting rim of the suprapubic box, making it more comfortable for the patient, and also a better "watertight" joint. It has been found, however, by experience, that an excess of urine tends to collect in the suprapubic box, and this difficulty has been overcome by fitting tubes, which pass through the sponge rubber pad.

In practice it is advisable to use the Hamilton-Irvine box without any "pads" for the first twenty-four hours after a prostatectomy, as large clots will not pass through the small tubes of the new-type pad. The Hamilton-Irvine box is placed in the reverse position (see illustration) when the pad is used.

PEPTALAC

Peptalac is an interesting new departure in dried foods. It is prepared from full-cream milk and wheat flour, each of which has been subjected separately to the action of pancreatic enzymes. The digested mixture is then dried to powder form. The simple addition of hot water to the powder gives a milk food in which a large proportion of the starch and proteins has been broken down to simpler forms. The trouble in arranging for peptonization of milk in the home is well known, for it is always difficult to get this done, and the efficacy of the digestion is usually very doubtful. "Peptalac" therefore represents a great simplification in the preparation of peptonized foods, and should prove popular with both the medical and the nursing professions. The makers (Cow and Gate Ltd., Guildford) give the following analysis of their product:

	Per cent.
Fat	22.5
Proteins	19.0
Digested proteins	8.0
Lactose	31.0
Starch and other converted carbohydrates	10.0
Mineral matter	6.5
Moisture	3.0

ANALYSIS OF SPINAL REFLEXES

The spinal reflex arcs, when isolated from the undoubtedly more complex cortical and subcortical regions of the brain, can still perform the fundamental reflex functions of which posture, progression, the scratch reflex, and the defence (flexion) reflex are examples. The study of these reflexes has provided most of our knowledge of the mechanism of the lower levels of the nervous system, and through this most of cerebral function is interpreted. In his Hughlings Jackson Lecture, printed in our opening pages to-day, Sir Charles Sherrington summarizes his more recent contributions to the conception of the mechanisms of activity of spinal reflexes.

The scientific analysis of motor reflexes begins with muscular function, for motor activity is used as the indicator of the reflex processes taking place. By new methods of investigation it is now possible to turn from analysis of the reflex movements to investigation of the numbers and situation of motor nerve cells involved, and, with these data, to seek further back in the reflex arc and to explore the combinations of excitation and inhibition which are in activity in various reflexes. Further still, with established data on motor discharge it has been possible to investigate the means by which afferent pathways, conveying stimuli from the sense organs to the central nervous system, can produce and vary finely co-ordinated movement and posture. Each motor nerve fibre is derived from one motor nerve cell (anterior horn cell or "motoneurone") and innervates a group of about 150 muscle fibres. The cell, its fibre, and the dependent muscle fibre group, act always as a whole, "the motor-unit," since discharge of the nerve cell necessarily implies contraction of all the muscle fibre group. It has been shown that the motor nerve cell (motoneurone) functions by discharging nerve impulses down the nerve fibre, either one at a time or in rhythmical series of impulses at variable rates up to eighty a second or more. Therefore the muscle fibres of each motor-unit may vary in activity from a twitch or series of unfused twitches (subtetanus) to a fused motor tetanus (maximal contraction). Each muscle is the executive implement of hundreds of such motor-units, and therefore variation in amount of contraction is possible in either of two ways. One is by alteration in the rate of discharge of the individual motor-units—that is, from twitch to unfused subtetanus to maximal contraction—and in reflexes this is studied by recording the action currents in nerve and muscle. Secondly, there is variation by change in the number of motor-units discharging at any one moment, and this is recorded by the isometric myograph (muscle tension recorder).

Of the aggregate of motor-units of any muscle (referred to as the "motoneurone pool" or "centre" for that muscle), one reflex causes one group or "fraction" to discharge, and another causes another fraction to discharge. The fractions usually overlap to varying extents, each of the overlapped motor-units being discharged by one of two or more reflexes. In this way the individual muscles are "fractionated," and thus, taking for instance the flexor muscles of a limb, a certain stimulus which produces flexion of the limb causes the discharge of a fraction of the motor-units in each flexor muscle. Another stimulus, which also produces flexion of the limb, likewise needs only a fraction of the units of each flexor muscle to produce its effect, but in this case uses a different group in each muscle. The fractions may include some units common to both reflexes, or, in other words, some units where both reflexes overlap, and these overlapped units are termed "occluded" units, for when already taking part in one reflex they are occluded from the other reflex. Thus the motor-units in a muscle can be labelled as belonging to this or that fraction, and can be recognized when they come into contraction by the relationship they bear to selected test reflexes.

The motor-units defined in this manner have been used to examine the processes of excitation and inhibition. These "plus" and "minus" processes in any single motor-unit result from impulses arriving by branches of large numbers of afferent pathways, and are in the nature of states existing in the region where the motoneurone has the afferent channel linked to it, a region called the synapse. Such a state lasts a finite but relatively short period, during which a certain amount of excitation can add itself to a state of excitation already at the synapse, or can "neutralize" a certain amount of inhibition. According to present ideas it is only when the sum of the excitatory states reaches a certain level, or threshold, that the motoneurone begins to discharge impulses, and so causes the motor-unit to evidence contraction. Below this threshold level the state of excitation of the motoneurone is "subliminal," and no contraction occurs; above the threshold level it is submaximal or maximal, according to the rate at which the neurone is provoked to discharge. It is found that besides the reflex fraction of a muscle provoked to discharge in a given reflex there are large numbers of motor-units provoked at the same time to a subliminal state by the same afferent impulse stream. This extra fraction in a subliminal state is termed the "subliminal fringe," and the term "fraction" is limited to the units actually discharging. Since the subliminal fringe is readily thrown into contraction by the overlap of any other subliminal fringe produced from another source, these units become the deciding factor in the niceties of co-ordination between different reflexes.

Every afferent nerve is composed of a bundle of nerve fibres, each derived from one or more sensory nerve end-organs, and each fibre branches widely at its central end to come into functional relationship with

enormous numbers of motor-units. One afferent fibre alone probably can never provoke discharge in any of these units, but fibres of like function from neighbouring end-organs overlap to such a degree that their concurrent function will cause discharge. The subliminal excitatory effect of one afferent source on a motoneurone can only sum with a similar effect from another source during the very small fraction of a second for which it lasts, and therefore the relative time of arrival of afferent impulses in the central nervous system adds a further complicating factor to the already complex distribution of latent effects. In some reflexes the timing of the afferent impulses determines the quality of the reflex. For instance, a large muscle twitch, the tendon jerk, can be produced by a sharp tap which provokes an afferent impulse from a number of stretch receptor organs in the muscle at the same moment, while sustained stretch of the same muscle produces only a feeble contraction (muscle tone), or no contraction at all. In the tendon jerk the central arrival of an impulse in many afferent fibres at the same time (synchronous afferent volley) can cause a great many more motor-units to discharge than the straggling series of waves arriving by the same fibres in response to sustained or slowly increased stretch.

The analysis of reflexes by these quantitative methods foreshadows a great advance in the experimental investigation of the action of therapeutic agents upon the nervous system and also explains many obscure clinical phenomena. The return of the knee-jerk in a tabetic patient, following a hemiplegia, is an example of the subliminal fringe converted to a discharging fraction by the addition of a fringe of tonic excitation from brain-stem centres (spasticity). Above all, with a better knowledge of the mechanism of nerve processes comes a better understanding of the exact place at which particular effects can be produced, and this is vital for advance in very many urgent problems in neuropathology and treatment. One has only to consider the bizarre phenomena of post-encephalitic states to realize how great these problems are. Sir Charles Sherrington's lecture is worthy of Hughlings Jackson, alike in philosophy and in vision, and we foresee the commencement of the application of quantitative physiology to clinical neurology with as fruitful results as Hughlings Jackson obtained from the application of qualitative physiology to cerebral and spinal localization.

THE POSITION OF MEDICAL OFFICERS OF HEALTH

Among essential conditions for the proper performance of the work of a medical officer of health are these: that he should not be liable to be faced with a position in which his action in regard to the health interests of the community he serves may conflict with his regard for the interest of any individual to whom he stands in the relation of private medical attendant; and that his tenure of office should not be in any degree at the mercy of anyone whose private advantage may be affected by the advice he tenders, or the action he recommends, on matters of public health. It is mainly for these reasons that not only the British Medical Association, but also the Ministry of Health, and its predecessor the Local Government Board, have for many years held that a medical officer of health should have reasonable security of tenure in his office, and that the post itself should be a whole-time appointment, or, to use the words of the Local Government Act, 1929, "that every medical officer of health shall be restricted by the terms of his employment from engaging in private practice as a medical practitioner." The admirable work done over a long period of years by part-time medical officers of health is gratefully recognized, and in all its pronouncements on this subject (especially at the Representative Meeting in 1911) the interests of existing holders of such part-time appointments have been regarded, and safeguarded, by the Association. Partly in consequence of this, the movement for the substitution of whole-time for part-time medical officers of health has progressed even more slowly than was anticipated; and the desirability of a much more rapid rate of advance in this direction found expression in the evidence given by Sir Arthur Robinson before the Royal Commission on Local Government, in the second report of that Commission, and in Section 58 of the Local Government Act, 1929, which was based on that report.

A further reason for the establishment of this principle, and for immediate action to give it practical effect, is to be found in the greatly enlarged duties and responsibilities which have of late years been placed upon public health authorities, mental health authorities, education authorities, and maternity and child welfare authorities, and upon their medical officers. These new duties have accumulated so fast that the continuing existence of a large number of very small sanitary authorities has become increasingly inconvenient, and a new type of medical officer of health, of much wider experience, both professional and administrative, is required if the work is to be well done. This is one reason why the public health service ought to be regarded as a single whole, and not as a series of disconnected localized arrangements, so that, while full use is made of part-time local medical practitioners in clinical work, administrative experience in departmental work may count for promotion, and the higher offices in the service be appropriately filled.

The Local Government Act, 1929, which adds still wider responsibilities to those of medical officers of health, carries the matter much further. The section above referred to provides that every medical officer of health hereafter appointed shall be precluded from engaging in private practice. The conditions under which this part of the Act is to be brought into effect, and the methods by which its objects can be secured, are the subjects of a memorandum just issued by the Ministry of Health to the councils of counties and of county districts. The contents of the memorandum

are noted and explained in an article on page 42 of this issue of the *Supplement*. It is important that all medical officers of health, all members of the public health service, and all members of public health local authorities should familiarize themselves with Section 58 of the Act, and with this memorandum setting forth the methods by which the provisions of that section may be carried into effect, for they will lead to numerous changes in the appointment of medical officers during the next few years. It is particularly important to note the various forms which combined appointments may take. There can be no doubt that the circumstances of county districts differ so widely that any one of the methods set forth in the memorandum might be both convenient and legitimate in certain cases, but there are indications that the Ministry's opinion as to the method to be preferred is not the same as the opinion of the British Medical Association and of the Society of Medical Officers of Health. The Association and the Society favour the method of combining adjacent districts so that one medical officer of health may be appointed to the combined district, or the same person appointed to the office by each of the districts concerned; while the Ministry appears to emphasize the advantages of appointing as district medical officer of health one who at the same time holds the post of an assistant medical officer to the county council under the county medical officer of health. With regard to the latter method it need only be said here that the divided responsibility and loyalty, the differing security of tenure of the offices held, and the difficulty of adjusting salary, expenses, and conditions of service, constitute grave disadvantages from which the alternative method is practically free.

FRACTURES OF THE FEMUR AND PELVIS

A useful and extended review of this subject was published recently by Dr. H. Earle Conwell of Fairfield, Alabama.[1] The regrettably large number of such injuries in America makes this study desirable. In this series of eighty-five cases, affecting eighty-six femurs, thirty-six of the children were injured by motor vehicles. The author describes and discusses various methods of treatment, quoting various authorities, and sums up, after saying that the literature is "unlimited," by classifying methods as: (*a*) those by plaster cast only; (*b*) those by plaster cast and extension by means of adhesive strapping, callipers, or Steinman's pin; and (*c*) by suspension and extension. All give excellent results, but (*c*) is the most popular. Treatment by open reduction should be the last resort, and is usually not necessary. Plaster casts give better results in the very young child than in the older, but plaster casts with extension give better results in the older child. Up to the age of 10 or 11 suspension and extension give better results than plaster casts with or without extension. Every case of fractured femur should be considered an emergency and treated immediately. Reduction should be done under anaesthesia. Conservation of muscle and of joint movements is of great importance, and physiotherapy is consequently advisable. Good alignment is essential, and, next in importance, bone approximation. It is definitely concluded that compensatory lengthening does take place, as also correction of poor alignment, but chiefly in patients before the age of 8 years. Finally, the extension and suspension method is by far the most comfortable, and facilitates examination, dressings (in case of compound fracture), and the use of radiant light (sic), hot baths, and active and passive movement. The same author, in association with Dr. Lloyd Noland,[2] chief surgeon to the Tennessee Coal, Iron, and Railroad Company, has published an interesting study of 125 cases of fracture of the pelvis treated in the course of eight years with a mortality of twenty, including six deaths from severe associated injuries. A cursory survey of the statistics gives some interesting information. For instance, it is illuminating to find that 71 out of the 125 fractures were sustained in industrial occupations, while 54 so-called "civilian" cases were no doubt mostly caused by motor vehicles. From the year 1920 to 1923 women had supplied only 10 per cent. of these fractures, whereas in the five years 1923–28 they formed nearly half of the cases, indicating probably, not an increase of rashness or decrease in skill, but a much increased use of motor vehicles by women. A rather unexpected conclusion come to by the writers is that in the motor car accidents pelvic fractures in women "were definitely caused by trauma of less severity than that producing such features in men." At first sight it is difficult to explain this difference, for although the long bones of the female are generally more slender than those of the male, it might be expected that the pelvis, which plays such an important part in reproduction, would be accordingly resistant. As in fracture of the long bones so in those of the pelvis, it has been found that although anatomical correction of displacement of bone may have been imperfect, functional results have been good. The overhead pelvic suspension frame was used in all these cases with satisfaction. As for that frequent complication, injury of the urethra or bladder, early drainage and suture have given encouraging results.

THE INTERVERTEBRAL DISCS

The results of work done since 1926 with the aid of a British Medical Association research grant are incorporated in an article on the intervertebral discs, by Mr. N. Ross Smith of Bournemouth, in the current number of the *British Journal of Surgery*.[1] Mr. Ross Smith examined, macroscopically and microscopically, discs from the thoracic and lumbar regions of the spines of fifty-seven persons, whose ages at death ranged from 1 to 86 years. Observations were thus made on the mode of nutrition, the normal and pathological anatomy, and the state of the discs in successive age-periods. Further, a series of skiagrams was collected showing the normal and various abnormal appearances of the discs. In the study of the normal anatomy, the discs were seen to be composed of three parts, histologically distinct—namely, the central

reticulo-gelatinous nucleus pulposus, the peripheral fibro-cartilaginous annulus fibrosus, and the upper and lower hyaline cartilaginous plates applied against the cancellous tissue of the vertebral bodies. Confirmatory of Luschka's observation of a central cavity in the disc, there was noted in microscopical sections of young healthy discs a space in the nucleus pulposus, the wall of which resembled synovial membrane and gave off villi. In contradiction of the generally held view that the discs are nourished merely by diffusion currents from the spongiosa of the vertebrae, channels containing blood cells were seen and traced from the spongiosa through the cartilaginous plates between the fibres of the annulus into the nucleus pulposus. In the plates, these were lined by a single layer of elongated cells, and both red and white blood corpuscles were seen in the lumen; but in the annulus and nucleus no cellular lining was seen, and white corpuscles alone were present. The state of the discs in different age-periods varied considerably. In the first decade the discs were biconvex, highly compressible and elastic, having a clear, white, finely fibrous annulus, thin translucent bluish-white cartilaginous plates, and a colourless, amorphous, gelatinous nucleus, sharply defined from the annulus. In the two following decades little change was noted, except some coarsening of the annular fibres and whitening and toughening of the nucleus from early fibrosis. In subsequent decades most of the specimens were increasingly coarsened, and the seat of pathological change, resulting in diminished elasticity, flattening, discoloration, and hardening or softening. But in a few subjects, even as late as the eighth decade, discs were seen little changed from the state in young subjects. The highest incidence of change was in the period 50–70 years. The changes were more frequent and severe in males. They were as common and severe in the thoracic as in the lumbar discs; but the discs in the two regions were not always affected simultaneously or to the same degree. The pathological changes observed were fibrous, cartilaginous, calcareous, bony, fatty, necrotic, and liquefactive. Increase in coarseness and amount of the fibrous tissue was a marked change in most specimens, as was increase in the number and size of grouping of the cartilage cells in the nucleus and annulus; but the relative amounts of fibrous and cartilaginous tissue varied widely. In the nucleus the fibrous tissue tended to assume a whorled form; in the plates, fibres transformed the matrix. Cartilage cells were seen in clumps of several cells, or in great masses forming nodules; these were noted in all parts of the disc, and were often atrophied, necrosed and liquefied with formation of ragged cavities, or calcified. Central calcification of a disc was not observed histologically, nor was complete bony transformation; but ossification of the external layers of the annulus and the anterior longitudinal ligament was present in one specimen. Deposition of fat in the fibro-areolar tissue of the nucleus was common. The following *x*-ray appearances were noted: (1) normal—a clear, biconvex space, sharply defined above and below by the even edges of the vertebral bodies; (2) thinning and flattening; (3) peripheral calcification; (4) central calcification; (5) obliteration by ossification; (6) diminished transparency with evidence of subacute inflammation of the adjoining vertebrae; (7) thinning, flattening, and diminished transparency with vertebral osteochondritis; (8) abnormal biconvexity with rarefying lesions of the vertebral body, such as osteoporosis, osteomalacia, carcinoma, and compressed fracture. From the observations outlined above, and from study of the literature, Mr. Ross Smith draws the following conclusions: The discs are rudimentary universal diarthrodial joints, highly important for the flexibility of the spine, and acting also as buffers between the vertebrae. The mode of nutrition is by blood channels derived from the vertebral spongiosa. Fibrous, cartilaginous, calcareous, bony, fatty, necrotic, and liquefactive changes are present in the discs of most individuals after the age of 30 years. A change noted radiologically is central calcification, termed "calcinosis intervertebralis." Inflammatory lesions have been seen in influenza and typhoid fever. Osteochondritis of the spine is an affection of the discs as well as of the vertebrae. Some reciprocal adaptability exists between the discs and the vertebrae when either are diseased. There is some relationship between affections of the discs and certain other diseases, notably arterio-sclerosis, osteoporosis, osteochondritis, and chronic rheumatic arthritis. The discs when healthy accentuate the effects of rarefying lesions of the vertebral bodies. Changes in the consistency and elasticity of the discs are responsible for much of the loss of suppleness of the body in middle and old age; these must be reckoned a cause of back pain and stiffness, and may account partly for the symptoms in spondylitis deformans and other chronic affections of the spine. Lastly, diagnosis of lesions of the discs depends on *x*-ray examination, the appearances being as enumerated above.

THE "BULLETIN OF HYGIENE"

It is an almost inevitable consequence of the present rapid expansion in scientific research that most workers find it frankly impossible to keep abreast of the growing volume of literature. As a result there is often a lamentable ignorance among workers in specialized departments of what their colleagues in other countries are doing. Not only does this involve much unnecessary duplication of work and the publication of articles that add nothing to existing knowledge, but it leads to a narrowness of vision which places a serious handicap on anyone who is endeavouring to solve the major problems of his subject. Meetings of learned societies and international congresses may supply a partial remedy for this state of affairs, but they are clearly insufficient and demand more time and expenditure than most people are able to afford. The most promising solution seems to lie in the publication of journals devoted to abstracts of current literature. Provided the field covered is sufficiently wide, and the papers to be summarized are selected with real care, there is every reason why such journals should prove of very real value to the research worker. The *Bulletin of Hygiene*,[1] which is now entering on its sixth year, was founded with this express object in view. It embraces a wide sphere, containing signed abstracts and reviews of publications on all branches of public health and preventive medicine. Periodicals and reports from all parts of the world are surveyed;

[1] Published by the Bureau of Hygiene and Tropical Diseases, Keppel Street, Gower Street, London, W.C.1.

and though attention is directed mainly to publications in English, French, and German, an effort is made to notice the more important papers in other languages. In order to render its contents even more useful, the *Bulletin* has now decided to rearrange its subject-matter in such a way that it is possible to run rapidly through the abstracts on any given branch of preventive medicine, and, by the authors' index which is provided, to pick out abstracts of papers by any worker whose contributions it is desired to follow. The *Bulletin* is published monthly at half a crown; the January issue contains 120 pages, and the subscription for the whole year is one guinea. This journal is in its own field unique; it is not as well known as it ought to be; and it deserves much wider support from the medical profession than it has hitherto received. We hope that in the future its real value will be appreciated, and that it will meet with the recognition to which its very capable management entitles it.

RICKETS AND ORAL SEPSIS

An inquiry by a committee of the Board of Education into the association of rickets and dental disease with adenoids and enlarged tonsils was the outcome of a previous investigation made by Dr. G. C. M. M'Gonigle in 1927. The report of Dr. M'Gonigle had demonstrated a close association, in children of school age, between certain slight bony abnormalities and the incidence of enlarged tonsils and mouth breathing. In the present investigation[1] nearly 1,500 unselected children, aged 5 years, were examined for bony deformities by three medical officers, Dr. J. N. Dobbie, Dr. E. J. Boome, and Dr. D. G. Leys, working independently; the examination of the nasopharynx was made by Dr. Wells, chief aurist to the London County Council, and of the teeth by Mrs. Mellanby. Nine bony abnormalities were included as indicative of rickets, and the number of these displayed by each child was taken as a standard of the degree of rickets present, although it was realized that a single sign in a relatively severe form might be more significant than two or three signs present to a less marked extent. The conclusions to be drawn from the findings of the observers are interesting but not dramatic. Adenoids, for example, were found with equal frequency among children free from rickets and among those showing one or more bony signs, and the incidence of adenoids, either mild or severe, did not increase with the number of bone changes present. On the other hand, severe adenoids occurred more frequently among children with two or more bony signs than among those free from rickets; and the highest incidence of severe adenoids was among 242 children showing four or more bone changes. The incidence of dental caries in 1,177 cases showed a small but steady increase from 4.62 per cent. in children without adenoids to 4.86 per cent. in children with adenoids severely infected. It was also found that caries and dental hypoplasia were more extensive in those children whose tonsils were septic, and the incidence and extent of caries increased with the severity of the septic condition. The committee concludes that dental and tonsillar sepsis may have a common cause, or that the tonsillar condition may be secondary to that of the teeth. As might be expected, a definite association was revealed between defects of the temporary dentition and rickets; the severity of both caries and hypoplasia increased fairly steadily with the degree of rickets, the incidence of caries rising from 92 to 96.6 per cent. If the bone signs may be regarded as an indication of deficiency of vitamin D in the diet, it appears that extensive enlargement of the pharyngeal tonsil occurs with somewhat greater frequency among children showing such signs of deficiency as rickets and dental disease than among others. But recent work goes to show that a sufficiency of vitamin A—which is closely associated in the diet with vitamin D—is necessary for the maintenance of a healthy condition of the mucous membranes. It seems as though a deficiency of these two fat-soluble vitamins may be responsible for the incidence of both rickets and adenoids, or at least that such a deficiency is one of the factors tending to produce an overgrowth of adenoid tissue. The investigation, though providing no overwhelming evidence in favour of the association of rickets and adenoids, has indicated an interesting line of inquiry. The fact that adenoids occur at least as commonly in better-class schools as in those of the poorest class suggests a discrepancy in the theory of a deficiency of fat-soluble vitamins responsible for both conditions. But the members of the committee believe that other factors, as yet unexplored, may mask the influence of vitamins, and may be active in affecting all classes alike.

THE SOCIETY OF APOTHECARIES

In the fine old oak-panelled hall of the Society of Apothecaries of London a large company assembled at a livery dinner which was held on January 27th to meet the Lord Mayor, Sir William Phené Neal, and the Sheriffs. The Master, Lieut.-Colonel C. T. Samman, was in the chair, and was supported by the wardens, Colonel E. C. Freeman and Dr. Cecil Wall. After the usual loyal and patriotic toasts had been honoured, the Master, in a brief speech, proposed the health of the Lord Mayor, Sheriffs, and the Corporation of the City of London, reminding the company that it was three years since they had been honoured by the presence of these dignitaries at a livery dinner. In reply, the Lord Mayor, remarking on the antiquity of their surroundings, made the suggestion that the portraits of historical personages which were so prominently displayed might be hung elsewhere without loss of beauty, in order to show up the grandeur of the oak panelling. The diploma of the Society (*honoris causa*) was presented to Sir John Lynn-Thomas, F.R.C.S., who, in reply, interested his hearers by a description of his early days of apprenticeship to an old-fashioned apothecary. Although he went to the London Hospital at a later date, his first experiences of medical practice were in a little Welsh village, where he was taught the principles of bloodless surgery. Dr. Henry S. Wellcome was presented for the Honorary Freedom of the Society by Professor W. E. Dixon, F.R.S., who referred to him as a great medical and social benefactor, his name a household word all over the world, his patriotism during the war an example to everybody. In reply, Dr. Wellcome reviewed some of the advances of medical science in his time, and

said that the war had taught lessons of undoubted value for the days of peace. As a memorial to their uncle, the late Dr. George Wilks (Past Master), Dr. G. W. Cock, on behalf of the Misses Lepard, handed over an early eighteenth century coffee-pot and several pepper casters, which had formerly been in the possession of the Society. Dr. Bramley Taylor accepted the gift for the Society. The health of the guests was proposed by Dr. Cecil Wall and was responded to by Earl Russell.

SIR ANDREW BALFOUR

Sir Andrew Balfour, of whom a memoir appears at page 245, was a valued worker for the British Medical Association. He held office as vice-president of the Section of Tropical Medicine at the Annual Meeting at Birmingham in 1911, and as president of the corresponding Section at Edinburgh in 1927. He was a member of the Post-Graduate Committee in 1925, and of the Ship Surgeons Post-Graduate Training Committee appointed in 1929. On behalf of the Association he compiled a *Guide to Courses and Qualifications in Public Health and Tropical Medicine and Hygiene*, and last year he delivered the Sir Charles Hastings Lecture, taking as his subject "Health and Empire."

We regret to record the death, at the age of 77, of Sir A. Garrod Thomas, M.D., LL.D., consulting physician, Royal Gwent Hospital, Newport, and formerly member of Parliament for South Monmouthshire.

THE PSYCHOLOGICAL FACTOR IN DELINQUENCY

A JOINT DISCUSSION

On January 23rd a meeting was held at the Friends Meeting House in London. The chair was taken by Dr. ISABEL WILSON, who explained that the Committee on Psychological Medicine of the Medical Women's Federation had, at a recent meeting in Lincoln, discussed the subject of delinquency. As a result of that discussion it had seemed reasonable to arrange for a meeting between the committee and certain probation officers who were interested in a psychological course given for them at the Tavistock Clinic.

Dr. MARY BARKAS said that there were two points that she would like to hear discussed: What was being done? and, What ought to be done for the different types of case with which probation officers had to deal? A certain proportion of cases were sent to remand homes or put into supervised occupations; a considerable number did quite well under those conditions. Psychiatrists found that the difficulty with their patients was often mainly one of environment, and nervous disorder might disappear if the environment were adjusted. There had been much dispute about the problem of the existence of moral deficiency. Dr. Barkas thought that there were certain types of high-grade defectives with a good general intelligence whose capacity for developing wisdom and judgement did not reach beyond the stage of reward and punishment. She would like to hear the opinion of probation officers on how these cases responded to the various methods of treatment. They seldom benefited much from individual intensive psychotherapy. It seemed that some adjustment of the reward and punishment mechanism was what would lead them towards the best citizenship of which they were capable. A second difficult type was the psychopathic or neurotic delinquent suffering from obsessions, compulsions, anxiety, or morbid fear. These definitely responded to treatment if it was available. But if they were to be treated they needed to be in some protected environment while the treatment was going on. Dr. Barkas wanted to know how far probation officers found that there was a lack of facilities of this kind. There were very few places where a child could be sent for this sort of treatment.

The Magistrate's Difficulties

Mrs. RACKHAM (Cambridge) said that in looking back over ten years on the Bench, one of the things by which she was most struck was the contrast between the court as a machine for finding out whether the prisoner was guilty or not, and the court as a machine for finding out anything at all about the prisoner. In the first capacity it was very good—not perfect, but as a rule it found out the truth. But—and a very big "but" it was—it was a very ineffective instrument indeed when it came to knowing anything about the prisoner, especially about his mind; why he did what he was charged with, whether he was likely to do it again, and how to prevent him from doing it again. Magistrates found it very difficult to know in what cases to seek expert information. They could not tell from the look of the prisoner—nobody looked his best in the dock—and unless he presented an imbecile appearance the magistrates did not know whether he was a mental case or not. When was the best time to call for a mental report? It was agreed that this was after the case had been proved and before sentence was passed. At that point it was possible to obtain the prisoner's record and sometimes to gather useful information from items in it, such as the school standard reached and any history of institutional care. In that case there must be a remand, which could not be for more than eight days. The question therefore arose: Where was the examination to be made? A prisoner over 16 years of age could only be remanded to prison—a very unsuitable place for a mental examination. To be sent to prison on remand was a great shock, especially for anyone who had not been there before. The surroundings might be equally bad in the home, where the relatives might be hostile to the whole idea of examination. There was a very great need for some more suitable place to send cases on remand. There were homes for children under 16, but these were very often at the police station or at a Poor Law institution, neither of which was ideal for the purpose. The Departmental Committee on Young Offenders had urged this as one of the most urgently needed reforms in our penal system.

The next question was: Who was to make the examination? There was a difficulty in securing a mental specialist. If the remand was to prison, the obvious person to make the examination was the prison medical officer or police surgeon, who, in a small place, would be a general practitioner of the town, who had not necessarily given time to this special work and who was likely to think that all that was required of him was a report whether or not the prisoner was certifiable under the Mental Deficiency or Lunacy Acts. A further complication was the question of fees. Many magistrates would think that the police surgeon ought to take this sort of case in the course of his duty without any extra fees. Having gone to the trouble and expense of getting a report the magistrate did not know how to act on it. There might be no local facilities whatever for treatment. If the child was to be taken to a child guidance clinic there must be somewhere for it to live while it was attending. Against all these difficulties there was the alternative and obvious way of proceeding to penalty, which was perfectly simple and involved no trouble or expense. The temptation was very great.

The committee on offences against children and young persons had found cases in which a man had been sent to prison for the same kind of sexual offence ten, thirteen, and fifteen times, with an occasional flogging thrown in. It was all wasteful and futile. Such cases made one

despair of the present system. From every point of view it was essential to find some better and more scientific way of dealing with problems of that sort. Another difficulty was that all magistrates did not yet grasp the importance of this kind of mental work. They were apt to misunderstand it, and on the one side to regard it as an attempt to shut people up for the rest of their lives, which they did not deserve, and on the other side as an attempt to undermine and weaken man's responsibility.

MRS. STORMONT (probation officer, Great Marlborough Street Police Station) spoke on types of delinquent, and described her work with shoplifters and prostitutes.

Interrelation of Magistrate, Doctor, and Probation Officer

Mr. CHINN (probation officer, Birmingham) said that there was great need for co-operation between magistrate, doctor, and probation officer in the treatment of delinquency, but it would be difficult to give evidence of existing co-operation. A growing concern for the right treatment of delinquency was apparent, particularly in juveniles and young persons. There was, however, a wide diversity of opinion as to what constituted right treatment. There was on the one hand a small minority of advanced opinion concerned with the scientific application of expert knowledge to the problem of the reformation of the delinquent, and, on the other hand, traditional repressive measures were widely used. In between these two extremes were several experiments, more or less developed, the aim of which was the reformation of the delinquent. Probation represented the community's attempt to reform the offender by a process of re-education in his own environment. Such a process would depend for its success on the co-ordinated contributions of what might be called the "healing" forces of the community, which would include the magistrate, the doctor, and the probation officer, and it would have to be used with discrimination. Probation should never be used without first taking into account the personal and environmental history of the offender and his physical and mental condition. That meant that no person should be placed on probation without a preliminary investigation being made, and only then after careful consideration of his suitability for that kind of treatment. There was a fairly general lack of understanding of the true meaning of probation, and in many provincial districts its use was very limited. There was still an impression in the minds of some magistrates that probation might be all very well for children and young persons, but that it was useless applying it to adults. Preliminary social investigations and medical histories were available in some juvenile courts in the large cities, but rarely, if ever, was an adequate investigation made in adult cases. It was even exceptional for investigations to be made in children's cases; apart from one or two of the large cities, children were tried and dealt with forthwith. No provision was made for medical help, and it was sometimes difficult to obtain expert advice. The only method open to the court needing medical advice was often to remand the offender in custody for an examination by the local prison medical officer. But even where this was done the quality of the advice given might detract from its value, and the court soon lost confidence in unsatisfactory reports. There were certain local prisons, listed as observation centres and having mental experts on their staffs, which might be used by specified areas. Such centres were more often employed by the large towns than the rural districts, and their scope was limited. The period of observation was bound to be short. The doctor's report might contain an accurate diagnosis of the offender's mental condition, but it rarely contained a practical recommendation, and no provision was made for treatment. Treatment, of a sort, might be obtained from the Poor Law authority if the offender was destitute or could be made to appear so, and certain obvious cases could be dealt with in the county mental hospitals. There was evidence that the administration of the Mental Deficiency Act was far from satisfactory in many counties. The number of mental experts qualified to give advice and treatment seemed to be surprisingly small, and they were seldom available outside the large cities. He would go further and say that very few mental experts realized how valuable their contributions could be in the treatment of delinquency. They too often confined themselves to a diagnosis. It was of little value to a probation officer—however gratifying—to receive from a doctor in the form of a report a summary of his own notes on the case. The probation officer wanted to know not only what was the matter with the offender, but also what he was to do about it. He should be able to look to the expert for constructive advice and treatment. If the reformative material available was to be used wisely and effectively it was essential to realize the interdependence of the court, the doctor, and the probation officer. There was therefore an urgent need for co-operation, and for all concerned to learn each other's language. The magistrate should understand the importance of treating the offender as an individual; the doctor by practical advice and recommendations should endeavour to make his contribution effective; and the probation officer, by working in close co-operation with both, should gain the necessary knowledge, not only to recognize cases of mental disorder, but intelligently to interpret the findings of the doctor.

The Clinic for the Delinquent Child

Dr. FLORENCE STACEY-CLEMINSON (Hull) asked whether a clinic for children would not be better started from the educational side as a school clinic, to which the courts could send children, rather than in connexion with the children's court. The children would not then be branded. Hull was trying to get the education authority to set up a clinic, but there were financial difficulties. At present, cases were sent to the psychologist attached to University College, but there was no definite clinic.

Mr. CHINN said that there was as yet no place in Birmingham to send children to for psychological treatment, but it was hoped that one would soon be started by the education authority. It was much better for an outside authority to conduct this than for the court to have its own clinic.

Dr. WILLIAM MOODIE said that neither the court nor the school authority was the proper body to conduct a clinic; the work should be done by someone entirely separate from both. It could not be done by any one individual, either psychologist, doctor, or social worker. These people must be available both separately and together, and they must co-operate. The doctor knew a certain amount, but not everything. A doctor with a general medical training was not capable of giving an opinion on a mental case, even a simple one. The required training was quite beyond the limits of the medical curriculum. Even with a special training he was not capable of giving an opinion on special educational problems, for the background of the educational problem was education. Every child was an individual and at the same time a school child, and had two aspects. One could be dealt with by the doctor, the other must be dealt with by the educational psychologist. In his work at the child guidance clinic he had found that the great bulk of delinquency resulted from environmental causes and not from a cause intrinsic in the individual. This introduced a third type of investigation: skilled social environmental investigation. What really seemed to matter was the environmental factor, and by manipulating the environment and the education it was possible to alter the behaviour in the desired direction. He wished to stress the point that the examination of delinquents was not purely a medical question.

A number of probation officers and magistrates took part in the subsequent discussion, and contributed their personal experiences. There was very general agreement on the need for increased co-operation between magistrate, probation officer, and doctor, and for the education of public opinion on the very important problem of the psychological aspect of delinquency.

Nova et Vetera

THE EYESIGHT OF THE BRONTËS

Recently my attention was drawn to some spectacles in the Parsonage Museum, Haworth, which had belonged to the Brontës. I took them to Mr. Read of the optical department of Messrs. Reynolds and Branson (Leeds), who kindly examined them for me. The quotations are from Clement K. Shorter's *The Brontës : Life and Letters*, published by J. M. Dent and Sons, Ltd.

Charlotte Brontë showed early signs of myopia. Mary Taylor, a schoolfellow at Miss Wooler's, Roehead, says: "She could not see the ball at games. When a book was given her, she dropped her head over it till her nose nearly touched it, and when she was told to hold her head up, up went the book after it, still close to her nose." This was in 1831, when Charlotte was 15 years old. In July, 1848, Charlotte and Anne paid a visit to London, in order to correct some misstatements regarding the authorship of the different novels. They were taken to the opera by Mr. Smith of Messrs. Smith and Elder, publishers. Charlotte writes regarding the people there: "They must have thought us queer, quizzical-looking beings, especially me with my spectacles." Mrs. Gaskell writes, *circa* September, 1853: "Charlotte Brontë cannot see well, and does little besides knitting. The way she weakened her eyesight was this, when she was about sixteen, she copied copper-plate engravings out of annuals." We can conclude that the following belonged to Charlotte:

1. Steel spectacles with twin pinsides.
   Right −7.5D. Left −7.5D.
2. Silver gilt single square reading glass with twisted handle.
   −7.5D.
3. Reading glass, folding joint, double glasses in dark tortoise-shell frame [this pattern was in use from 1835 on].
   Right −10D. Left −10D.

Patrick Branwell Brontë also wore spectacles, as we see from a silhouette portrait of him. The following pair was probably his:

Spectacles. Silver rims, sliding sides, pebble glass.
Right plano. Left −4D.

The first mention of the Rev. Patrick Brontë's sight is in Emily's diary for July 30th, 1845: "Papa has a complaint in his eyes." In August, 1846, Charlotte writes: "In a fortnight I hope to go with papa to Manchester to have his eyes couched. Emily and I made a pilgrimage there a week ago, to search out an operator, and we found one in the person of Mr. Wilson. If he judges the cataract ripe, we shall remain, if not, papa must remain in darkness a while longer." Mr. Wilson, M.R.C.S., was honorary surgeon to the Manchester Infirmary from 1826 to 1855. She writes on August 21st from Manchester: "Mr. Wilson pronounced papa's eyes quite ready for operation." On August 26th: "The operation is over; Mr. Wilson performed it. The affair lasted precisely a quarter of an hour; it was not the simple operation of couching, but the more complicated one of extracting the cataract. I was in the room all the time." On September 13th: "Papa thinks his own progress rather slow." They returned to Haworth on September 28th. In November of that year she writes: "Now to see Papa walk about independently, read, write, etc., is indeed a joyful change." Six years later (April 12th, 1852) she refers to it again: "My father was seventy at the time he underwent an operation; he could not believe that at his age and with his want of robust strength it would succeed. A day seldom passes that he does not express gratitude and pleasure at the restoration of that inestimable privilege of vision whose loss he once knew." The last reference is dated March 18th, 1854. She writes: "My dear father's vision is not perfectly clear, but he can read, write, and walk about, and he preaches twice every Sunday."

There are five pairs of spectacles that we concluded must have belonged to the Rev. Mr. Brontë:

1. Silver rims (date mark 1809).
   Right +1.5D. Left glass missing.
2. Short loop end sides, round eyes, diameter 33 millimetres.
   Right +5D. Left +5D.
3. Loop end, silver frame, with blue tinted glasses.
   Both +5D.
4. Steel pair, double hinged.
   Right +6.5D. Left +6.5D.
5. Silver, sliding side.
   Right +5D. Left +13D.

No. 5 makes it evident that the left eye *only* was operated on for cataract.

Menston, near Leeds. Honorary Secretary, Bronte Society.

India

Progress of Madras Hospitals

At the end of 1929 there were 1,128 medical institutions at work in the Presidency of Madras—namely, 188 State-public "institutions and 29 "State-special" institutions; 756 municipal, local fund, and rural institutions; 34 private ones, which were aided, and 68 which were not; and 53 railway dispensaries. The number of dispensaries increased during the year by thirty-nine. With a view to improving the facilities for medical relief the Government took over the administration of twelve local fund and municipal hospitals and dispensaries, in addition to the 106 medical institutions similarly "provincialized" in 1928. In his annual report for 1929, Major-General C. A. Sprawson, I.M.S., surgeon-general to the Government of Madras, remarks that the efficiency of subsidized dispensaries varies considerably according to the medical officer in charge. There are three itinerant dispensaries in the Presidency, and medical officers in charge of regular dispensaries which do not provide enough work to engage their whole time, pay visits to neighbouring villages on specified days in the week to deal with the sick poor. The total number of patients treated for leprosy during the year was 16,552. As the result of the leprosy survey work, new clinics have been opened in four places, and there is an increasing demand for the supply of leprosy experts to various districts. It is proposed to appoint a leprosy propaganda officer to travel through the Presidency, and co-operate with the local medical authorities in establishing clinics and educating the public. Honorary medical officers have been appointed in all district headquarters hospitals and Government hospitals in the mufassal. In some districts there are medical libraries, and the number of books available for circulation has been increased during the year. Major-General Megaw, I.M.S., has introduced a method of testing the strength of quinine solutions at dispensaries during inspection. When first brought into operation this unexpected check revealed widespread fraud by compounders, and exposed the fact that in many cases patients were getting only a portion of the dose prescribed; a considerable improvement has been noticeable in this respect—at any rate, during the times of inspection. In his annual report of the Government General Hospital, Madras, for 1929, the superintendent, Lieut.-Colonel E. W. C. Bradfield, I.M.S., calls attention to the fact that there has been a satisfactory reduction in the cost of treating patients. Although during the last ten years there has been a steady rise in the number of cases of injuries, due probably to the greater prevalence of motor transport, evidence is obtainable from the figures that traffic control is improving and diminishing these risks. The training of

medical students continues, but it is noted that there is an increasing tendency to overload the curriculum with lectures and laboratory classes at the expense of important clinical subjects, particularly in the third year. The classes are, moreover, still handicapped by the small size of the temporary lecture hall in the out-patient department; this difficulty will continue until progress can be made in the enlargement and rearrangement of the hospital. Improvements in the venereal clinic have enabled it to undertake first-class work, and to make a serious attempt to tackle the problem of venereal diseases in Madras.

Malaria as a Cause of Infantile Mortality

A considerable portion of the annual report for 1929, by Dr. J. S. Nerurker, executive health officer for Bombay, is devoted to the incidence of malaria and its sequels in that city. While he recognizes that the figures obtained from medical practitioners as the result of an inquiry cannot be too strictly relied upon, owing to the frequent transfer of patients, yet it seems to be clear that malaria is widely prevalent. He remarks that the high rates of infantile mortality in various races resident in Bombay, among the richer as well as the poorer classes, suggest that some additional adverse factor must be present, beyond the poverty and the maternal ignorance about health which are chiefly responsible for high mortalities in Western countries. Dr. Nerurker believes that this factor, which seems to affect all classes, is probably malaria, but he adds that the practice of soothing babies by the administration of opium still continues extensively among the more ignorant portions of the population. With a view to detecting conditions prejudicial to the life of infants, home visits are paid by the municipal district nurses, and cases of sickness among women and children are promptly dealt with. Inquiry is made at these visits about the condition of newborn infants, and instruction is given to the women with regard to the care and rearing of children. Confinements are attended, help is provided during the lying-in period, and assistance is rendered by maternity homes, infant milk depots, and welfare centres. As the result of these measures the infant mortality in Bombay has been decreasing, but it is pointed out that it is difficult to bring about further improvements owing to the fact that the overwhelming majority of the infantile deaths under 1 year are not certified by medical practitioners.

King Edward VII Memorial Hospital, Bombay

The importance of further co-ordination of institutional medical treatment in Bombay is emphasized by the report of the King Edward VII Memorial Hospital for the year 1929–30. Both in the wards and in the out-patient departments there has been very serious congestion, and despite the fact that nearly 1,000 new beds have been made available in Bombay during the last five years the demand for further hospital accommodation is increasing. An arrangement has been made between the Corporation and the committee of the Helpless Beggars' Camp by which unclaimed and helpless patients may be transferred to the care of this organization. Early cases of pulmonary tuberculosis are now sent to the Turner Sanatorium, and patients suffering from advanced stages to the Maratha Hospital. Part of the overcrowding in the Memorial Hospital is due to the number of fracture cases which occupy the beds for several weeks at a time. It is suggested that a convalescent home is urgently needed for such patients, even if no more than thirty beds are thereby freed. Another urgent necessity is the provision of an infirmary for the chronic and nervous cases. As regards the congestion in the out-patient department, it is hoped to build shortly a separate casualty department and to extend the surgical dressing section.

England and Wales

Dinner to Sir Marriott Cooke

Sir Marriott Cooke, K.B.E., M.B., whose office as Commissioner of the Board of Control terminated on the coming into operation of the Mental Treatment Act on the first day of this year, was entertained at dinner by his late colleagues on January 26th at the Café Royal, London. Sir Marriott Cooke joined the Lunacy Commission in 1898, became in 1913 a Commissioner of the Board of Control, of which he was chairman during the years 1916–18, and continued as an unpaid Commissioner after his retirement in 1921. The object of the dinner was to mark the affectionate esteem in which his late colleagues hold him, and their sense of his devotion to the cause of those suffering from mental disorder during his many years of public service—a period which, including the period spent as medical superintendent of the mental hospitals at Devizes and Powick, extended to fifty-six years.

West London Hospital Extension Scheme

The West London Hospital is proposing to celebrate its seventy-fifth anniversary by large extensions, including the building of a new wing with separate rooms for 100 paying patients. After consultation with the medical and surgical staff, whose generous spirit in the matter is acknowledged by the chairman, Sir William Wells, the board has decided that patients will be admitted to the private rooms at an inclusive rate, seven guineas a week being the minimum. This rate will include the provision of medical and surgical treatment, specialist services, and drugs, as well as nursing and maintenance. It is anticipated that, including the twenty-six private beds which the hospital already possesses, at least 1,300 paying patients will be accommodated every year. Prospective patients, it is believed, will regard it as a great advantage to learn beforehand the amount of *liability*. The provision of a paying wing is not the only scheme on foot. The whole frontage of the hospital is to be rebuilt, and there the administrative offices and certain other departments are to be accommodated, while the general wards which have overlooked the main road at Hammersmith are to be removed to a quieter position. The hospital possesses the land necessary for the extensions, but from £150,000 to £200,000 will be needed to complete the scheme, and at a festival dinner to be held at the Guildhall on May 12th it is hoped to raise £50,000 as an instalment sufficient to allow an immediate start on the work. The paying beds are expected to be self-supporting, and they may, indeed, provide a surplus, which will be devoted to the upkeep of the free beds. The West London Hospital has an average of 4,000 in-patients a year and 40,000 out-patients, and costs £55,000 to maintain, towards which the endowment and thank-offering and almoner receipts amount only to £18,000.

New Woolwich Housing Estate and Health Centre

On February 14th the Minister of Health is to cut the first sod of the new housing estate of the Woolwich Borough Council, situated at Eltham, and open a new health centre which has been erected by the council on its present housing estate, adjacent to the new site. The present estate consists of 2,186 houses, but as this is not sufficient to meet the demands for new housing accommodation, a further property of 275 acres has been secured, upon which it will be possible to erect 2,200 houses, the average density thus being eight to the acre, including provision for open spaces. The new health centre, which is situated in an open part of the present housing estate, is said to be the first in London of a type specially

designed and equipped to provide also for school medical service, thereby linking up in one building the medical supervision of the school child with the care of the child of pre-school age. The building has been constructed to deal expeditiously with large numbers, and rooms for dental work and the treatment of minor ailments can be used when necessary for the twofold purpose of the school and of the welfare services. The borough of Woolwich has already seven welfare centres, which in one year had a total of 52,079 attendances.

London County Council Public Health Staff

The London County Council has been reorganizing and strengthening the staff of its public health department. In view of the steady growth in the work of the tuberculosis section, and its large increase as a result of the transfer of functions under the Local Government Act, certain rearrangements have been made, and the head of the section has been given increased emolument. The officer engaged upon the supervision of the scheme for the treatment of children suffering from diseases of the ear is to be made a principal assistant medical officer at the normal salary of £950, rising by £50 annually to £1,250 a year. Attention has also been given to the staffing arrangements consequent upon the decision that the work of medical examiner shall be performed in the public health department. It is pointed out that it is essential that this work shall be undertaken by a highly experienced officer, possessed of considerable clinical skill, and competent on occasion, when legal actions arise, to support his opinion against that of eminent members of the profession. The proper rank for this position is considered to be that of principal assistant medical officer. A year ago the council created several positions of area medical officer, but left them for the time being unfilled. In June last it was decided that one of the positions should be filled, and now, in view of the great pressure of work in connexion with the general hospitals, it is recommended that another position be filled. The salary which the position carries is £1,700 a year.

The Mental Hospitals Committee of the London County Council has made a special grant of £150 from the accumulated interest on the Maudsley Hospital bequest account for certain research work, for six months in the first instance, with a view to a standardization of tests to differentiate at the onset of mental illness between patients destined ultimately to become chronic cases and those suffering from transient conditions. A medical officer has also been detailed for twelve months for research work upon post-encephalitic cases and the administration of special treatment to such cases at West Park Mental Hospital and the Manor, Epsom. Another assistant officer has been detailed, at Claybury Mental Hospital, for research work on the respiratory reflexes.

Scotland

Health in Schools

Under the auspices of the Glasgow Branch of the Educational Institute of Scotland an address on public health and the school was delivered, on January 29th, by Dr. A. S. M. Macgregor, medical officer of health for Glasgow, who mentioned that school medical inspection and treatment was started about twenty years ago in an attempt to deal with defects among children. From being concerned with minor defects and malnutrition, this service had gradually expanded to include the care of crippled, rheumatic, and delicate children, for whom large subsidiary services now existed. These efforts had resulted in a steady improvement in the general health of the school child. Defects had lessened materially in degree—for example, the majority of the defects now registered as slight would have been ignored in the early days of school inspection, while there were fewer actual cripples. The principle underlying the association between preventive medicine and education was to secure a clear conception of the rudiments of health, and to apply these to school life as far as possible. The real guardians of health were those who controlled systems of education, who built schools, and who arranged curricula; above all, those who taught and guided children. Public health depended more and more on the training received in the schools.

Retirement of Edinburgh Professor

At a meeting of the University Court of Edinburgh University on January 26th, it was intimated that Professor Arthur Robinson, M.D., intended to retire from the chair of anatomy at the end of the current academical year. After graduating M.B., C.M. with honours at Edinburgh University in 1883, Professor Robinson became a demonstrator of anatomy under Sir William Turner in Edinburgh, and shortly afterwards took up a position in the anatomical department of Owens College, Manchester. He was awarded a gold medal for his thesis when he proceeded M.D. in 1890, and he later became a Fellow of the Colleges of Surgeons of both Edinburgh and England. In 1896 he was appointed lecturer in anatomy in the Middlesex Hospital Medical School, and in 1900 professor of anatomy at King's College, London. Four years later he was elected to the chair of anatomy in the University of Birmingham, and in 1909 he was appointed professor of anatomy at Edinburgh. Professor Robinson early turned his attention to the study of mammalian embryology, and was awarded the Neill Prize for 1925–27 for his work in this subject. He has written and edited several books on human anatomy, and has contributed extensively to scientific journals.

Edinburgh Royal Infirmary

A committee, appointed by the court of contributors to the Edinburgh Royal Infirmary, has issued its comments on the annual report of the managers of that institution. The managers view with some concern the increasing number of persons awaiting admission to the wards, which in the past year amounted on the average to 2,851, and they consider that the difficulties can be overcome only when the proposed expansion of the infirmary has been accomplished. It is pointed out that motor accidents were responsible for 446 cases treated in the infirmary, excluding a large number treated as out-patients. The cost of maintaining the infirmary was £151,765 in the past year, compared with about £60,000 in pre-war years. Of the annual revenue about 20 per cent. is stated to be derived from interest on invested capital; about 47 per cent. from voluntary contributions; about 11 per cent. from payments by patients and revenue from students' fees; the remaining 22 per cent. had to be met by legacies. Of the various sources of revenue, it is considered that contributions from voluntary sources can be most easily increased, and that legacies should be regarded as a means of building up a capital reserve. In this connexion the increased annual expense which will follow the expansion of the institution is referred to. The average cost per bed during the past year was £155—an increase of about £5 on that of the previous year. This sum included £48 for provisions, bedding, and general equipment; £23 for nursing and service; £30 for medical and surgical expenditure; £11 for radiological services; £23 for overhead charges; £10 for management; and £9 for taxes, insurance, etc. The arrangements for

incorporating the Maternity and Simpson Memorial Hospital with the Royal Infirmary have now been completed, and the site of George Watson's College will be available for the contemplated extension at the autumn term of the present year. It is stated that some years must elapse, however, before the extension can be carried out. In view of the large capital expenditure required and the fact that the Royal Infirmary can be used as a national radium centre for Edinburgh, approved by the National Radium Commission, the managers have decided to abandon the scheme of reconstructing Beechmount House as a radium institute. During the present year Lady Findlay has been appointed permanent chairman of the board.

At a meeting of the General Court of Contributors to the Royal Infirmary in Edinburgh on January 26th Lord Provost Whitson, who presided, mentioned that an early pronouncement would be made in regard to the question of paying patients. Referring to the proposed extension of the Infirmary he said that another effort to raise funds was being organized, and that this was intended to appeal to the small subscriber.

Earl Haig Memorial Hospital

A new maternity home for Hawick and district was opened on January 16th by the Duke of Roxburghe. The inception of the home dates from 1927, when a sum of £2,000 was given by Mr. Norman W. Grieve to establish a maternity home for the town and district on condition that it should be dedicated to the memory of Field Marshal Earl Haig. For this purpose premises already used by the local nursing association and for the provision of maternity service and child welfare were taken over and adapted. Treasurer Fisher (Hawick), chairman of the Public Health and Public Assistance Committee of the county, who presided, remarked that this was the first ceremonial gathering of the new County Council of Roxburgh. In declaring the building open, the Duke of Roxburghe said that the home was the first-fruit of the amalgamation between the burgh and county authorities, and that it had been rendered possible by the generous support of Mr. Grieve.

Appointment of Regional Medical Officer

The Department of Health for Scotland has appointed Dr. James L. Halliday to be one of its regional medical officers (medical referees). Dr. Halliday is an M.D. of Glasgow University and holds the D.P.H. From 1922 to 1924 he was assistant resident physician at Ruchill Fever Hospital and Sanatorium; from 1924 to 1926 clinical officer in the Glasgow Public Health Department; and from 1926 to 1929 medical officer for the Southern Division of Glasgow. At present he is senior assistant in the Public Health Department of Glasgow Corporation.

Development of Veterinary Art

In an address on the establishment and development of veterinary education, delivered on January 22nd to the Edinburgh University Agricultural Society, Dr. J. Russell Greig, director of the Moredun Animal Diseases Research Institute, said that the legal code of Hammurabi, dated about 2100 B.C., contained references to the treatment of oxen and asses and to the amount of the veterinary's fees. The art was mentioned in the writings of Hippocrates, Aristotle, and later Roman authors, and the Romans had regular veterinary practitioners in the service of the legions, known as veterinarii. In *Hippiatrika* the veterinary knowledge of the Byzantine Empire was gathered together by Constant VII, and in 1530 this work was printed by order of Francis I of France. Veterinary schools and hospitals for sick horses were established at Lyons and at Paris after the middle of the eighteenth century. Sainbel, a Frenchman, founded a school in London in 1793, which was attended by William Dick, an Edinburgh farrier. Dick subsequently began a course of lectures in Edinburgh with four students, and was appointed a lecturer in 1821 when the Highland Society provided a grant of £50. It was from this modest beginning that the Royal (Dick) College—now one of the foremost veterinary schools in the world—had developed. Organized veterinary research, as distinct from education, had come into being within the last ten years, and collaboration between the veterinary and medical professions was rapidly becoming more intimate. Veterinary science was proving an integral part both of agriculture and of comparative medicine.

Milk for School Children

The Education Committee of Edinburgh Town Council on January 26th approved of an experimental scheme for the supply of milk to school children. A report by the medical officer of health and the education officer pointed out that any scheme adopted under the Act of 1930 had to be framed in accordance with certain restrictions. They recommended, therefore, that as an experiment the necessitous children on the free food roll of the infant departments of two representative schools in congested districts should be supplied, free of charge, with one-third of a pint of milk each during the forenoon interval, and that the other children in these departments should receive the same quantity on payment by their parents of the cost of the milk. The milk would be delivered in sealed bottles of one-third pint capacity, and straws would be provided for drinking it. The quality of milk used will be Grade A (tuberculin tested), and the cost to parents will be one penny a bottle.

Correspondence

THE OUTLOOK ON TUBERCULOSIS

SIR,—I note that you have been favoured by several letters on the subject of my recent lecture. The remarkable widening of outlook on tuberculosis which has occurred during the past fifty years as the result of intensive clinical, pathological, and experimental work has had practical consequences in the adoption in Great Britain of the National Tuberculosis Scheme. The scheme, which is comprehensive in scope and of general applicability, now functions more or less effectively throughout the land. Notwithstanding the difficult times we have passed through since its institution, and the evident inequality of machinery and personnel in different parts of the country, satisfactory results have been obtained. Everything considered, it may be said with justice that the antituberculosis scheme of Great Britain covers the ground and meets the varying issues more completely than methods which have been introduced elsewhere. It was not the purpose of the lecture to discuss the elements of the scheme. These are sufficiently known to all. The object was to draw attention to the further laps on the road, and to show that these were well in view and, in fact, had been amply tested for the purposes of general traffic.

In commenting on the lecture, your correspondents have inclined towards the one-corner view. As happens not infrequently, they appear to have read into the words conceptions other than those of the writer, and have proceeded to criticize the position. I would respectfully disclaim responsibility for this. A sympathetic correspondent urges that "a new orientation is needed," and invites me "to give the necessary lead." I had hoped,

Sir, that the lecture gave more than a lead. I had hoped that the emphatic negative given to the question, "Have we reached finality?" and the development of the subject in the subsequent pages would have been readily recognized as constructive. Those pages, read in connexion with previous proposals by me, notably in the *Journal* of March 24th, 1923 (p. 493), contain, as it seems to me, an unanswerable plea in favour of the systematic watch for, and determination of, the fact and date of initial infection (tuberculization) in every child. The further point is pressed that the object of this systematic determination is to render possible the adoption of measures for anticipatory detuberculization. Because of the predominant part played by tuberculosis epidemiologically, the principle underlying anticipatory detuberculization is that the fact of tuberculization entails the thoughtful interpretation of any aberration from perfect health during the further life of the child, and the studied endeavour to maintain resistance by every available means, *including, when it seems desirable, the use of* tuberculin as an immunizing agent. The value of tuberculin, and the methods of anticipatory application, are especially developed in the earlier paper.

During each academic year some two hundred undergraduates are taught by me to believe that the cause of the accumulation of pronounced and incurable cases of tuberculosis of every form, which so heavily overweights the antituberculosis scheme, is neglect of those fundamental considerations. The student is enjoined that it should be a primary duty of the family doctor—or his equivalent—to watch for the fact and date of tuberculization as something likely to occur and readily determinable, and, following such determination, to keep the fact in view throughout the further life-history of the individual in order that, if indications of progressive tuberculization supervene, they may timeously be met by measures of detuberculization.—I am, etc.,

University of Edinburgh, Jan. 31st. R. W. PHILIP.

SIR,—In the interesting letter by Dr. D. J. Gair Johnston of Birkenhead in your issue of January 24th there appears the following sentence:

"Again, the general practitioner, *who should receive every* encouragement to familiarize himself with the earliest signs of tuberculous infection, not merely tuberculous disease, is persistently kept in the background in this as in all other branches of preventive medicine."

This statement of Dr. Johnston's is not true for Lancashire, and, from my own experience, other parts of England. If I may be allowed to give concrete proof in respect of the former area, I quote a letter sent to every medical practitioner in the administrative county of Lancaster by the clerk of the county council in which the following paragraph, amongst others, appeared:

"The Tuberculosis Committee desire me to thank the general practitioners for their co-operation in the past, as the success which has so far been achieved under the scheme would not have been possible without their help; and they are anxious that such assistance should be continued and further improved in the future, particularly in regard to the reference of cases or suspected cases of tuberculosis to the tuberculosis officer at the dispensary so that any necessary treatment available under the scheme may be commenced whilst the patient is in the early stage of the disease. The tuberculosis officer will always be pleased to meet you in consultation in regard to any case of difficulty or doubt."

In 1929, 86 per cent. of new cases were sent, *before* statutory notification, to the tuberculosis officers for an opinion as to diagnosis. Further, in that year there were 982 personal consultations between general practitioners and tuberculosis officers.—I am, etc.,

Preston, Jan. 27th. G. LISSANT COX, Central Tuberculosis Officer.

SIR,—Dr. John Gibbens, in his letter published on January 24th (p. 156), assails the weak spot in the defence when he says:

"The earlier the age at which a positive reaction is found, the more likely one is to find the adult that is disseminating the infection. It is mainly through the early detection of these adults that reduction in the incidence of tuberculosis in childhood will eventually occur."

How fares it with these adults? Possibly they are suffering from some mild "chronic bronchitis" of long duration; or "asthma with bronchitis"; or they may even have had that strange disease "double pneumonia three times"! If tuberculosis is not detected in the child at an early age, the erring parent who is resistant possibly continues at work till the age of 50, 60, or 70, and dies of "chronic bronchitis and broncho-pneumonia"—the unrecognized cause of a more acute form of pulmonary tuberculosis in the children when they are about 20 or 25, or even of tuberculous meningitis in the grandchildren. In such circumstances the family cease to notice the cough of the parent, but the children crawling along the floors encounter the tubercle bacilli, which enter by the usual channels. Air-borne disease or infection by milk are of collateral interest in such a household.

By notification the patient is conducted to the parting of the ways. Outside criticism may give us some index to our shortcomings. In his "Campaign against Tuberculosis in England" (1930, *Jahresbericht Tuberkulose-forschung*), Dr. E. Stolkind, in a review of the notifications for 1928, points out that "these numbers are found to be the lowest recorded for thirteen years," and says:

"In my opinion the number who died from pulmonary tuberculosis should actually be much higher, as so often death from this disease is put down to chronic bronchitis. There is no other country where so many deaths are notified as being from chronic bronchitis."

In the present state of civilization, it would at times seem wellnigh an outrage to notify a parent as suffering from doubtful pulmonary tuberculosis.

Bronchial discharge of any duration should always be suspect. In spite of the endeavours of many eminent men the public receive but little enlightenment on things that matter, because the truth has often such an unpleasant flavour. The public accepts its medical education from novelists. The Victorian novelists who entertained the mothers of the race depicted consumption as an interesting disease, with a central figure, the heroine, who patiently awaited the inexorable laws of fate as she "declined" day by day. Sometimes the end was hastened by a clean but dramatic haemorrhage. Melodrama flies from the more disagreeable facts. Even the press still applauds the consumptive marriage *in extremis*, and the public and the clergy add their blessing.

The real history of the disease and the collateral chest complaints of other members of the family are not paraded to the specialist; it is the family practitioner who knows, or should know, what the position of affairs really is.—I am, etc.,

Middlesbrough, Jan. 24th. J. M. MACPHAIL.

SIR,—In reading the correspondence provoked by Sir Robert Philip's recent lecture, it appears to me that we—or at all events the lay public—are in danger of forgetting certain essential facts. Owing to misunderstood propaganda there are a number of fallacies still current which have an important bearing upon the possibilities of control. Among these are the following:

1. That all tuberculous individuals are equally infective.
2. That infection is the sole cause of tuberculosis, whereas we all know that in the majority this is fostered or precipitated by non-tuberculous causes—largely such as the medical

officer of health and the sanatorium doctor or tuberculosis officer have been busily combating.

3. That infection with the tubercle bacillus always causes tuberculosis, whereas we know that most of those we meet are infected with tubercle but will never suffer from the disease.

4. That in the absence of tuberculous infection we should all be immune from the disease, whereas immunity is only possible through infection or specific inoculation, or by inheritance from those who have acquired immunity through infection. Generally speaking, exposure to tuberculous infection is hurtful, harmless, or even beneficial, according to the mode of infection and circumstances of the case. For illustrations see results at Papworth and at reputable sanatoriums. If at some future time there should be only an occasional source of infection, prophylactic injections would be of the first importance. At present general prophylactic inoculation might easily lead to the neglect of some of the other causes of tuberculous breakdown, and to waste of public money, quite apart from the doubt as to the harmlessness of the available vaccines.

5. That the early case of pulmonary tuberculosis always needs the shortest course of curative treatment, whereas the essential points are the teachability and character of the patient; we all know of early cases which, in spite of everything we can do, progress steadily to a fatal end.

In the last resort, immunity and recovery alike depend on constitutional resistance, not on infection, although the conditions of life and methods of treatment naturally have a great influence.—I am, etc.,

Farnham, Surrey, Jan. 31st. F. R. WALTERS.

TREATMENT OF CIRCULATORY FAILURE

SIR,—I read with interest the abstract of Professor Ritchie's address in your issue of January 31st (p. 195), in which he deals with the subject of acute circulatory failure. He states that the most frequent form of this condition observed by the medical practitioner is toxaemic shock, which may develop in acute infectious diseases, and especially in acute pneumonia. Professor Ritchie then proceeds to a description of the clinical facts in support of his belief that acute cardiac failure in pneumonia is often a direct sequel of failure at the periphery. With this hypothesis I am in entire agreement, but it seems to me strange that, in describing the treatment of the condition, Professor Ritchie, while mentioning such remedies as oxygen, carbon dioxide, the subcutaneous injection of strychnine, etc., omits any reference to those anti-shock measures which are really efficacious.

In the treatment of all types of shock, whether due to trauma, toxaemia, haemorrhage, or anhydraemia, I believe there is urgent need to adopt measures to increase blood volume. To realize that the severe weakness and fall in blood pressure in pneumonia is not necessarily or usually due to intrinsic cardiac failure, but is due to vasomotor collapse, should lead to the adoption of vigorous anti-shock treatment. Even though such treatment might embarrass a heart which is failing owing to intrinsic changes, it may be safely used in toxaemic shock to help the patient through the critical phase during which immune substances are being elaborated. The first step in the treatment is the intravenous administration of 50 c.cm. of a 50 per cent. solution of dextrose. The hypertonic dextrose solution rapidly draws fluid from the tissues into the blood vessels, and temporarily adjusts the blood volume to the capacity of the vascular bed. This method is most useful in medical shock of toxic origin, but the results are not so satisfactory in the anhydraemic shock of diabetic ketosis, because here the already dehydrated tissues cannot give up a satisfactory contribution of fluid to the blood stream. The above treatment usually requires to be supplemented soon after by giving 500 to 1,000 c.cm. of saline or glucose-saline solution into a vein, as recommended by Janeway in 1907 for treatment in infectious disease. This measure for controlling shock in pneumonia has not, in my opinion, been sufficiently exploited.

All administration for the treatment of shock, excepting such as may be additionally given by mouth, should be intravenous rather than subcutaneous or intramuscular. The extremely sluggish and greatly restricted peripheral circulation renders absorption by the subcutaneous route so slow that it may be regarded as practically closed. The use of vaso-constrictors, such as epinephrin, is not helpful, and may be dangerous, as they merely tend further to constrict blood vessels already contracted, to the disadvantage of the capillary circulation.

The ideal treatment of shock is, of course, blood transfusion, and the blood of any patient likely to develop shock should be grouped early in order to have a suitable donor in readiness.—I am, etc.,

Edinburgh, Jan. 31st. JOHN EASON.

TREATMENT OF VARICOSE VEINS

SIR,—Dr. Twiston Davies writes in the *Journal* of January 31st of tissue fluids of the lower limb "stagnant by virtue of (*a*) gravity, (*b*) 120 mm. Hg of arterial pressure, and (*c*) 48 inches of blood in the superficial veins (less any surplus capacity in the deep veins)." He is obviously considering a patient in the standing posture. The meaning of the phrase in parenthesis is obscure to me.

Measurements which I made many years ago showed that the arterial pressure in the leg is greater than that in the arm by a pressure which is equal to the height of the vertical column of blood which separates the two points of measurement. The increase of arterial pressure through gravity balances, then, any increase in venous pressure due to gravity, supposing such pertains, and the pressure in the arteries, produced by the heart, makes the blood circulate. The pressure due to gravity, which in the standing posture is equal to a column of blood as high as the man, tends, however, to dilate the capillaries and veins in the legs, and to increase transudation of tissue fluid. This tendency is counteracted normally by the skin and connective tissue which limit expansion, and by movements of the muscles which express blood upwards past the valves in the veins. Every structure in the body is arranged so as to make this expressive action effectual.

Movements and change of posture are, then, of first importance for keeping up the circulation and preventing stagnation, with consequent deficiency of oxygen and loss of healthy condition of the tissues. Varicose veins and ulcers result from long-continued standing or sitting required in certain occupations, the effect of which—that is, production of stagnation—is enhanced by poor nutrition. I have produced striking improvement in varicose ulcers by putting patients in an oxygen bed tent and letting them breathe this gas for many hours a day. By pulling tight the bandage, as recommended by Dr. Davies, the support is given which the skin and tissues have lost, and the blood is once more made to circulate effectually, particularly as the patient is ordered to get up and told to walk about. One can realize the important influence of muscular movements on the circulation by placing one foot on a chair while standing, and observing the blanching effect on the veins of the dorsal surface of the foot produced by raising the heel up and down. By such means, with the help of the valves in the veins, the capillary pressure can be kept as low in the feet as in the upper parts of the body. In the abdominal organs the respiratory movements and the contractions of the alimentary canal and the spleen have the "sponge-squeezing" effect, and are most important for preventing

stagnation. The deep breathing and muscular contractions of the abdominal wall produced by exercise provide a natural massage, the importance of which cannot be overrated.—I am, etc.,

London, Jan. 31st. LEONARD HILL.

SUBPHRENIC ABSCESS

SIR,—The valuable article in the current issue on subphrenic abscess, by Messrs. R. P. Rowlands and W. D. Doherty, leads me to point out what I have felt for a very long time—that the term "subphrenic abscess" refers to but one aspect or termination of a very much commoner process than is usually allowed—namely, subphrenic infection. This results from the usually accepted causes, but is also, in a mild degree, a fairly frequent complication of epigastric operations such as splenectomy, gastric resections, and cholecystectomies in which oozing from adhesions prevents us from leaving the bone-dry field which is our ideal; biliary extravasation is another cause which one found too frequent before one discarded the practice of tying a tube to the ligature on the cystic duct. There is no doubt that considerable amounts of extravasated fluids can be absorbed without infection occurring here; but in most cases, from the nature of the operation, infection is inevitable.

The symptoms of subphrenic infection are very clear, and of course they are the early symptoms of subphrenic abscess. Phrenic shoulder pain is practically constant, though transient; the patient will refer to stiffness in his neck, etc., but the surgeon must be very wary about this symptom. There is rise of temperature and pulse rate, and the patient looks "toxic." Rigidity and tenderness are often present at the costal margin. Pleural effusion is early; not the effusion that is capable of demonstration by percussion, etc. (*pace* the physicians!), but a slight serous fluid shown by a hypodermic needle. It may be observed that the development of a pleural effusion in an abdominal case that is "going wrong" is practically a certain indication of subphrenic trouble. Finally, if one has not too much confidence in one's clinical observations, the moral support of a leucocyte count may be obtained.

In view of the fact that a great many such infections recover without abscess formation, the practice of "cooking" such cases has obviously much to commend it; nevertheless the cases should be recognized early, and I submit that the diagnosis of subphrenic cellulitis or peritonitis is one that is capable of being made with confidence. Once it is made, a competent clinician should be able to determine whether and when resolution is taking place, just as he should in a case of appendicitis or cellulitis of the thigh. It should not be necessary to wait for radiographic evidence of diaphragmatic displacement, etc. With regard to the conclusions as to treatment put forward in the article, one must express complete agreement.—I am, etc.,

London, W.1, Feb. 1st. C. JENNINGS MARSHALL.

CATARACT OPERATION IN EXTREME OLD AGE

SIR,—As an addendum to the article by Lieut.-Colonel R. H. Elliot on cataract operation in extreme old age in your issue of January 24th, perhaps I may refer to the following case. In 1916 I extracted a cataract from an old lady of 93, with needling two months later. In 1926 her niece reported to me that she was still alive and well, at the age of 103, and reading to her companion, whose vision was defective. She lived till she was nearly 106, enjoying most of her faculties until within a month or two of her death. This case seems to illustrate the success with which the operation can be performed in extreme old age, as indicated by Colonel Elliot.

His further point, that in cataract cases in the seventies and eighties the duration of life sometimes seems to be shortened by the shock and other disturbances incident to the cataract operation, has also been my experience, as it no doubt is that of other ophthalmic surgeons.—I am, etc.,

Glasgow, Jan. 29th. A. J. BALLANTYNE.

SIR,—Lieut.-Colonel R. H. Elliot's article reminds me of my oldest patient for cataract operation. She celebrated her ninetieth birthday in the nursing home, and refused to allow a "keyhole" operation, as she called it. I therefore removed her cataract extracapsular through the pupil on June 30th, 1921, and did an anterior division operation, owing to her advanced age, on the eighteenth day after her first operation. On the day she left she told me that she had a walk with her husband in the evening, and could see all the vessels in the Forth. That was before she got her glasses, which she received a month later; with them she reached 6/6 and Jaeger No. 1, the smallest reading type. She returned to see me two years later, and said that she could not see with her glasses; on examination I found numerous scratches on the thick cataract glass caused by their being pushed into a metal chatelaine. She would not believe it until she felt them with her nails. She lived until she was 99 and was greatly pleased with the result of her operation, because for five years previous to it she had had to be fed and clothed, being quite blind from double cataract.—I am, etc.,

Glasgow, Jan. 29th. W. B. INGLIS POLLOCK.

FAMILIAL INCIDENCE OF CANCER

SIR,—I appreciate the points made by Mr. Lockhart-Mummery and Dr. Ludford. The former emphasizes the difficulty of establishing the exact nature of the tumour, but a growth which produces the signs of carcinoma and finally destroys the patient should be accepted as malignant, and malignancy is here more important than exact microscopical character. It is agreed that carcinoma may supervene on adenoma, but adenoma may itself follow chronic inflammation. Turnbull and Worthington, in discussing primary carcinoma of the liver, give the successive stages as cirrhosis, regeneration nodule, adenoma, carcinoma nodule.

With a principle of this kind as a guide the study of cancer families at once becomes important, for both the cancerous and non-cancerous members will be found to suffer from a variety of complaints which have a common feature in that they are chronic degenerations. For instance, mother and daughter have carcinoma; they and all the remaining brothers and sisters are thin, anaemic, and have partial stationary cataract. Again, a drunken father dies of ruptured umbilical veins, a son dies at 47 of carcinoma of the stomach, a daughter dies of the same disease seven years after hemiplegia, while the remaining son dies of ruptured aortic aneurysm. The important thing is the family diathesis, which produces an abnormal incidence of cancer, and the early results of a study on these lines persuade me that there is an infective agent awaiting discovery which, in the majority, is met by typical reactions with atrophy and degeneration, but in the minority the long struggle ends in metaplasia and malignancy.

So far the indications are that a common agent is the *Spirochaeta pallida*, which, owing to the chronicity of its attack, its power of exciting tissue proliferation, and its heritability, is well qualified to be suspect. It does

not die when the Wassermann reaction becomes negative, as clinicians incline to believe, but rather achieves symbiosis, and produces a type of family prone to malignant disease.—I am, etc.,

Caernarvon, Feb. 1st. GRIFFITH EVANS.

SEPTICAEMIA FROM MINOR WOUNDS

SIR,—When general septicaemia follows a minor superficial wound and a fatal result ensues, one cannot but be impressed with the tragedy of the case and the futility of the measures which we at present employ. Without going into great detail, two recent cases under my care appear to illustrate this.

Case A.—An apparently healthy man, aged 25, 14 stone in weight, sustained a scratch to his calf. He was seen three days afterwards, with a temperature of 104° F.; immediate treatment was instituted (antistreptococcal serum, etc.). He died four to five days later with a temperature of 110°. The wound on his leg had then healed. There was slight redness over the lymphatic area, no enlarged glands in the groin, no pain in the leg. One or two blisters appeared which, when the cuticle came away, left small, round, flat ulcers.

Case B.—An apparently healthy muscular man of 29, about 12 stone in weight, with a wound about two inches long above the patella, not involving the joint or the suprapatellar bursa. The wound was cleaned and sutured, and antitetanic serum was injected. Two days later the temperature was 103°, and the pulse 136. General antiseptic measures were started at once. The temperature fluctuated from 102.5° to 98.4°, and the patient died on the sixth day, presumably of heart failure. There had been no rigor. The lymphatic area was oedematous and brawny. Blisters appeared, and the skin overlying them broke. The glands in the inguinal region were not affected. The patient complained of considerable pain in the leg.

The measures adopted in the two cases included the following. *General:* (1) Normal horse serum; (2) antistreptococcal serum—various makers' serums were tried so that a large number of types of streptococci might be got, with the hope that the particular organisms at fault in this case might be included; (3) antiscarlatinal serum; (4) intravenous mercurochrome; (5) disulphamine. *Locally:* (1) Glycerin and ichthyol; (2) fomentations; (3) urea crystals; (4) Bier's hyperaemia. In the second case I made an incision down to the muscle, encircling about one-third of the limb on the anterior and medial aspect of the thigh, near the groin, with the object of cutting the lymphatics and preventing them from emptying their contents into the general system.

The question of amputation arises in these cases, and the surgeon is almost always in doubt, except at the very beginning and at the end. At the beginning he feels that no good would be done, and that serums, etc., should first be given a chance; at the end he feels that the limb should come off, but that the condition of the patient would not allow it. It is during the time between that the question really arises and should be answered, and the operation undertaken if it is to do any good at all.

I have written this note merely to ask questions, and in the hope that, if any discussion follows, some useful clinical help will result.

1. Would an ordinary blood transfusion be of any help in such a case?

2. Would an immune blood transfusion be better? (The donor is given an injection of vaccine made from the patient's organism, and consequently, it is said, his blood is richer in the specific antibodies which are most particularly required in this case.)

3. Would a vaccine be of any help? In both cases the patients died in less than a week, which does not give much time for preparing vaccines, etc. In the second case the lymphatics were all cut across, and yet this appeared to do no good. There were no glands in the groin. Is it that the injection was not travelling by the lymphatics? If not, why was there a red line along their track? And if it was not going by the lymphatics, why was there no enlargement of the groin glands?

Da Costain's lymphaticostomy for general peritonitis, in which he cut the thoracic duct at the neck, was proved to be a failure—in fact, the fluid that drained away was in some cases shown to be sterile and non-toxic. This is now explicable in view of the more recent work of Williams on the origin of the toxaemia of these cases arising not from outside the bowel, but rather from the *B. welchii* growing in the alkaline regions of the small intestine. Apparently lymphaticotomy in these cases is useless also.—I am, etc.,

Belfast, Jan. 19th. IAN FRASER, M.Ch., F.R.C.S.

THE "DEEP POOL" BATHS

SIR,—I should like to add my testimony to that of Dr. W. S. C. Copeman (January 24th, p. 158) with regard to the importance of "deep pool" baths in the re-education of muscle. I had the opportunity of supervising a large number of cases of paralysis and paresis of muscles due to spinal injuries at the Ministry of Pensions Hospital, Church Lane, Tooting. In addition to the advantages of warm water in relieving muscle spasm, etc., the mental effect on the patient of being able to float, and (with the support of an attendant) to assume an erect posture, is of incalculable value. Unfortunately, the Ministry saw fit to leave the building, and thereby a most valuable adjuvant to physical treatment was abandoned.—I am, etc.,

London, W.1, Jan. 30th. JOHN SAINSBURY.

MEINICKE CLARIFICATION REACTION

SIR,—With reference to Dr. David Prentice's article on the Meinicke clarification reaction in your issue of January 24th, I have done a number of the microscopical tests, but was struck by the frequency of the non-specific pseudo-positive results which I obtained. Definite positive serums were easily picked out, but there is an intermediate range of results which had to be read as positive (faint) which were definitely negative to the Wassermann and other tests. These non-specific results were very prone to appear when serums were not perfectly fresh or when one or two stray red blood cells were present in the serum.

The value of the rapid and simple test is not to be discounted, but I have found the Sachs-Witebski, a recent introduction at Heidelberg, much more reliable and even easier in performance than the Meinicke. The agreement of the Sachs-Witebski with Wassermann results has proved extremely close in my hands.—I am, etc.,

London, S.E.5, Jan. 29th. G. BOUSFIELD.

HOSPITAL POLICY

SIR,—For the complete elucidation of even the simplest of diseases, and especially for the earlier diagnosis of grave diseases, a more and more elaborate diagnostic equipment is becoming necessary. It is true, too, that for the efficient treatment of all disease an increasingly elaborate therapeutic equipment is nowadays required. For these as well as other reasons diagnosis and treatment of disease are becoming more and more institutional. It is true everywhere that a greater number of sick people are going into hospital than used to be the case. It is manifest that every medical practitioner, be he specialist or in general practice, must take an increasing interest in hospital work, and as a corollary to this there ought to be a workable hospital policy. Since 80 to 85 per cent. of hospital patients are of the insured class, for whose treatment under the National Health Insurance Act the general practitioner is responsible and is paid by the State, it

would seem reasonable that the Hospital Policy should be devised to suit the general practitioner as well as the specialist. The fact that general practitioners are ten times as numerous as the specialists would also seem to give them a claim to reasonable consideration.

The British Medical Association Hospital Policy has had a tremendous lot of work and thought expended on it, is full of useful detailed information and advice, but even in Great Britain I am afraid it is to a large extent a dead letter. Why is this? My opinion is that the Policy is too much one for consultants and specialists, and does not sufficiently cater for the general practitioners. The idea of a base hospital with clearing-house attached, and fed by a complete ambulance service, seems to me to infer that the general practitioner is not capable of making a diagnosis of anything but the simplest of diseases, and, if a diagnosis be made, is not capable of carrying out any active treatment more elaborate than the administration of a purge or the application of a poultice. Furthermore, it is well to remember that hospitals are run for the good of the patients and not for the convenience of specialists; and it is the comfort and convenience and happiness of the patients that should be the first consideration. My feeling, therefore, is that instead of centralizing the good class work in a base hospital it would be infinitely better in every way to decentralize it. Give the outlying hospitals up-to-date equipment and encourage the outlying men to undertake more advanced work, which, indeed, though handicapped in many ways, many of them are already doing. The result of this decentralization policy would, in my opinion, be good for the patients and for the medical profession at large, as well as good for the nation.

The centralization of good class work in a base hospital is in my opinion the first great mistake of the B.M.A. Hospital Policy. The second great mistake is the struggle to retain the moribund voluntary hospital system. The fundamental idea of that system is its dependence upon the charity of the public and of the medical profession for its support. The public who formerly gave of their charity to the hospitals are, in many cases, not in a financial position to do so any longer. The financial position of many of the voluntary hospitals, and the violent efforts that have been necessary of late years, even to the extent of lotteries, to keep them afloat at all, show that the upkeep of hospitals by voluntary effort is rapidly becoming a thing of the past. Yet the hospital service is an absolutely essential service. Now it is becoming increasingly recognized that the health and welfare of the worker is a matter of national importance. The social services include ante-natal clinics, maternity and child welfare work, national health insurance, the Workmen's Compensation Act, unemployment benefit, old age pensions, etc., and the cost of these per head of the population had risen from 14s. in 1914 to 91s. in 1928.

Of the voluntary hospital patients 80 to 85 per cent. are of the insured class, who have demanded as their right and have got the franchise, all the social services above mentioned, and a large say in the control of the industries of the country, and are consequently no longer entitled to charity. I believe that in other ways the effort to retain the voluntary principle is becoming a menace to proper hospital development. For all these reasons I am of opinion that the voluntary hospital system should be discontinued. Why not make the hospital work a national service, as has been so successfully done in Sweden and Denmark? It is quite manifest from reports that those countries have decentralized much of the hospital work, and that their State hospitals are vastly superior to our voluntary hospitals. The substitution of State hospitals for the present system would of course mean that all medical practitioners, whether specialist or general, would be adequately paid for their hospital work. In any hospital system it should be arranged that as many as possible, if not all, of the general practitioners should take an active part in the hospital work.—I am, etc.,

Ballymena, Jan. 29th. J. ARMSTRONG.

COMBINED TUBERCULOSIS AND ORTHOPAEDIC CLINICS

SIR,—May I be allowed to call attention to a practice that seems to prevail in certain districts in connexion with tuberculosis and orthopaedic clinics?

In this neighbourhood a tuberculosis clinic is held on Tuesdays which is attended by all classes of tuberculous patients, pulmonary and surgical, of all ages. When the clinic is ended the building is shut up, and the following morning the same waiting room, dressing rooms, and consulting rooms are occupied by numerous orthopaedic patients, many of whom are naturally in anything but robust health. The medical practitioners in the district have united in sending to the medical officer of health a communication calling attention to the risk which they consider is being incurred by the orthopaedic patients; but his reply indicates "that there is no cause whatever for alarm and that the general practice is being adopted here, and there is no possibility of considering the use of other premises."

I should be glad to know whether the general body of the profession approves of such a practice as above described, and if it is generally agreed that the orthopaedic patients are running no risk under such conditions. —I am, etc.,

Yeovil, Jan 30th. CHARLES J. MARSH.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

In the House of Commons this week the Representation of the People Bill was read a second time by 295 to 230. Sir E. Graham-Little and other University members spoke against it.

The Parliamentary Medical Committee met on February 3rd and recorded its regret at the death of Dr. Ethel Bentham. Dr. Howard Jones, medical officer of health for Newport (Mon.) addressed the committee on marine hygiene. At the instance of the Public Health Advisory Committee of the Labour party, the Parliamentary Medical Committee was asked to consider a draft Proprietary Medicines Bill, and decided to refer the subject to a future meeting. The question of the establishment of a Rheumatic Advisory Committee was also raised.

Shortage of R.A.M.C. Officers

Mr. SHAW, in reply to Dr. Fremantle on February 3rd, said that, excluding quartermasters, the establishment of officers of the Royal Army Medical Corps (Regular Army) was 863. The number of officers at present in the corps was 741, of whom 684 were regular officers, and the remaining 57 temporary commissioned officers and retired officers employed to mitigate the shortage. There was no establishment for officers holding temporary commissions; twenty-five vacancies for regular commissions in the corps were offered last month, but only five candidates came forward. The number of applicants for temporary commissions was very small.

Dr. FREMANTLE: Does the right hon. gentleman realize that that means that the Army is temporarily unfitted to take the field at the present time? Mr. SHAW: I recognize that the shortage of medical officers is grave, and that subject has been receiving very earnest consideration. Dr. FREMANTLE: The same answer has been given by successive Secretaries of State for War in this House.

Small-pox in London

Mr. GREENWOOD told Admiral Beamish, on January 29th, that the weekly notifications of small-pox in London had been at about the same level for the last three months, though they were lower than in the corresponding period of last year. Relatively to the population, the incidence of small-pox had recently been higher in London than in England and Wales as a whole. Replying to a further question, Mr. Greenwood said that the large majority of the cases of small-pox in recent London outbreaks were persons in whom no evidence was found of vaccination prior to infection. Of the remainder, some were vaccinated during the incubation period of small-pox, but too late to prevent the occurrence of the disease, and others had been vaccinated only in infancy. The latter were almost entirely adults, and included no person under the age of 11 years.

Pensions

On February 2nd Mr F. O. ROBERTS informed Dr. Morris-Jones that the power conferred by Article 4 of the Royal Warrant was exercised only when the Minister's medical advisers were satisfied that treatment which was necessary in the pensioners' interests had been unreasonably refused. No statutory rights as to increase of pension or, in case of the pensioners' death, to widows' or dependants' claims, could be created by an award made under special sanction. That did not prevent the Ministry from dealing with any later developments on their merits, and, indeed, the increased award was clear evidence of its readiness to take an equitable view of unforeseen contingencies.

Housing

Replying to Mr. Mills and others on January 29th, Mr. GREENWOOD said he had received from local authorities in England and Wales ninety-five resolutions declaring areas to be clearance areas within the meaning of Section 1 of the Housing Act, 1930. Resolutions had been passed declaring seventeen areas in London, occupied by 2,174 persons, to be clearance areas under the same Act. These resolutions did not require his confirmation. In addition, one improvement scheme under the old legislation, involving provision of rehousing accommodation for 2,632 persons, was confirmed after January 1st, 1929. Schemes resulting in the displacement of 400 persons during the next five years would be undertaken by the borough council of Kensington, which had already passed resolutions declaring two areas, involving 275 persons, to be clearance areas.

Replying to Major Glyn on January 29th, Mr. GREENWOOD said that returns of houses erected without State assistance were obtained only for half-yearly periods. The last year for which complete figures could be given ended September 30th, 1930, when 161,699 houses of a rateable value not exceeding £78 (or £105 in the Metropolitan Police district) were completed in England and Wales, of which 51,324 were erected with State assistance and 110,375 without State assistance.

Venereal Disease

In reply to Dr. Fremantle, on January 29th, Mr. GREENWOOD said that he had received representations from one voluntary association regarding the need for further propaganda by local authorities on the subject of venereal diseases. Surveys of the health services of local authorities now being made by inspectors of his Department included investigation of the educational measures undertaken in each area on health questions, including venereal diseases. If it appeared in any case that this was being neglected, prompt action would be taken. Until the surveys were completed it would not be possible to say in how many areas no propaganda on this subject was being undertaken.

Meat Inspection.—On January 29th Mr. GREENWOOD said that if any evidence was found, on inspection in this country, of the presence of caseous lymphadenitis in any portion of mutton and lamb, the whole piece should be condemned. He was not aware of any ports in England or Wales at which this recommendation was not put into operation, and he could not make any statement about further measure of control of imported severed parts of mutton and lamb.

Mental Disease.—Replying to Mr. Kinley on January 29th, Mr. GREENWOOD stated that research work was done in public mental hospitals, and particulars were published in the medical press from time to time and in the report of the Board of Control every year. He hoped that, with the co-operation of the local authorities, the services of medical officers in public mental hospitals might become available as consultants on out-patient treatment and other developments under the Mental Treatment Act.

Notes in Brief

The Home Secretary does not propose at present to take any action on the report of the Select Committee on Capital Punishment.

Mr. W. Adamson states that there are now more than fifty day nurseries and child gardens in Scotland, accommodating about 1,500 children, maintained or aided under maternity and child welfare schemes.

On February 3rd Miss Lawrence told Mr. Lambert that no bacterial standard was laid down for milk products as such, whether of home production or imported.

The Services

NAVAL MEDICAL COMPASSIONATE FUND

A quarterly meeting of the directors of the Naval Medical Compassionate Fund was held on January 28th, when Surgeon Vice-Admiral Sir Arthur Gaskell, K.C.B., O.B.E., K.H.S., Medical Director-General of the Navy, was in the chair. The sum of £90 was distributed among the several applicants.

DEATHS IN THE SERVICES

Colonel Hubert Oliver Browne Browne-Mason, D.S.O., R.A.M.C. (ret.), died at Cheltenham on December 9th, 1930, aged 58. He was born at Exeter on November 29th, 1872, was educated at St. Mary's, and took the M.R.C.S. and L.R.C.P.Lond. in 1896. He entered the R.A.M.C. as lieutenant on January 28th, 1898, passing first into Netley, and became lieutenant-colonel in the long war promotion list of March 1st, 1915, and colonel in 1922. He retired on December 26th, 1925. He served in the war of 1914-18 in Mesopotamia, took part in the first advance on Baghdad and in the siege of Kut, and was taken prisoner when Kut surrendered, but was released a few months later. He was mentioned in dispatches, in the *London Gazette* of April 5th, July 13th, and October 19th, 1916, and was given the D.S.O. in 1916. In 1924 he was appointed one of the honorary surgeons to the Viceroy of India.

Lieut.-Colonel Alexander Haldane Stokes, R.A.M.C. (ret.), died at Bedford on November 19th, 1930, aged 87. He was born on October 9th, 1843, and was educated at Trinity College, Dublin, where he graduated as M.B. and B.Ch. in 1868, and as M.D. in 1869. Entering the Army as assistant surgeon on October 1st, 1868, he became surgeon on March 2nd, 1873, when the rank of assistant surgeon was abolished, and surgeon major after twelve years' service, retiring on October 8th, 1890. After retirement he was employed at Sandown, Isle of Wight, from May 6th, 1891, to October 31st, 1907. He served in South Africa in 1881, in the Transvaal campaign in the first Boer war, when he was in charge of a base hospital, and was mentioned in dispatches; and in the Sudan campaign of 1885, at Suakin, when he received the Egyptian medal, with a clasp, and the Khedive's bronze star. While the old regimental system was still in force he served in the 44th Foot, now the 1st Battalion of the Essex Regiment.

Major Baman Das Basu, Bombay Medical Service (ret.), died in India on September 23rd, 1930, aged 63. He was born on March 24th, 1867, at Lahore, was educated at Lahore University and Guy's Hospital, and took the L.S.A. in 1888 and the M.R.C.S. in 1889. Entering the Indian Medical Service as surgeon on January 31st, 1891, he became major after twelve years' service, and retired on May 1st, 1908. He served in the Sudan, in the Dongola campaign of 1896, receiving the Egyptian medal and the Khedive's bronze star; and in the North-West Frontier of India campaigns of 1897-98, on the Malakand, in Buner, and in the action of Tanga Pass, receiving the frontier medal with a clasp. He was the author of many books: *The Study of Indigenous Drugs*, 1893; *The Plague in India*, 1905; *The Dietetic Treatment of Diabetes*, 1909, a very successful work, which reached its thirteenth edition in 1923; *The Story of Satara*, 1923; *The History of Education in India*; *Colonization of India by Europeans*; and, with K. R. Kirtikar, *Indian Medicinal Plants*, two vols., 1926.

Obituary

SIR ANDREW BALFOUR, K.C.M.G., C.B., LL.D.

M.D., D.Sc., F.R.C.P.LOND. AND ED., D.P.H.

Andrew Balfour has passed away at a time when the world can least afford to lose him. His loss will be acutely felt, not only in this country, but in the United States and abroad generally, for he was a man of a thousand friends. At the time of his death he was director of the London School of Hygiene and Tropical Medicine and an active member of innumerable committees, so that his passing makes a gap which will be filled with great difficulty, as he had come to represent a force of the first magnitude in the medical educational service of this country.

Andrew Balfour, the son of a well-known practitioner, was born in Edinburgh on March 21st, 1873. Educated at George Watson's College and the University of Edinburgh, he soon proved himself to be imbued with the *ingenuum pervervidum Scotorum*, a spirit to which he himself often referred as characteristic of the youth of his day. After graduating M.B., C.M. at Edinburgh in 1894, he joined his father in medical practice, but it soon became apparent that his inclinations were towards rather the prevention than the cure of disease. Having decided to devote himself to public health, he entered Cambridge University in 1895, and took the D.P.H. of that university in 1897. After performing research work under Kanthack on typhoid fever, he went for a period to Strasbourg. He graduated M.D.Edinburgh in the following year, his thesis on the toxicity of dyestuffs, with special reference to river pollution, being adjudged worthy of a gold medal. He followed this up by gaining the B.Sc. in public health.

The outbreak of the South African war found him serving as a civil surgeon in the Transvaal. From 1900 to 1901 he was on duty in the pestilential typhoid camp of Pretoria, where he himself suffered from a severe attack of the disease. Having obtained the South African medal with three clasps he returned to England, and, coming under the influence of Patrick Manson, became an ardent student of tropical medicine.

Balfour's next step on his onward career came with his appointment in 1902 as director of the Wellcome Tropical Research Laboratory, and medical officer of health at Khartum. Two years later he was appointed sanitary adviser to the Sudan Government. Here he formed a close friendship with Lord Cromer, Lord Kitchener, Sir Reginald Wingate, and other great men of that day. His career in Khartum lasted altogether eleven years, and it is safe to assert that this was the turning point of his career; he soon became known as "Balfour of Khartum." The amount of work he performed in organizing the health service of that city was stupendous. He succeeded in transforming the dusty, ill-kept, insanitary mud huts of the Khalifa into a model town, and banished malaria entirely from its precincts. His scientific output at this time was no less remarkable, and can be read in the four magnificent, scholarly, and well-illustrated reports of the Wellcome Tropical Research Laboratory, which appeared from 1904 to 1911. In the latter year he issued, in collaboration with Major R. G. Archibald, his second review of the recent advances in tropical medicine; this volume of 416 pages to some extent anticipated the work of the Tropical Diseases Bureau, which was founded in 1912, and of which he afterwards became sectional editor and member of the managing committee. It is recorded that so perfect were his antimalarial measures in Khartum that a fine of 10s. was instituted for every live insect which could be demonstrated in the European quarters of the city, and that he himself was forced to impose the first fine on himself when his inspectors found a single mosquito in his own residence. Among many measures which must be placed to his credit at this period was the institution of a floating laboratory, a gift from Dr. H. S. Wellcome to the Sudan Government, in which he and his colleagues explored the upper reaches of the Nile. This may be taken as the period of his greatest scientific activity. His best work was done on the blood, for he realized that many of the faults in stained blood films were due to fallacies and contaminations. His work on spirochaetosis is still regarded as a classic. A great believer in the granular phase of these organisms, both in the blood of birds and of man, and in its subsequent development in the tick, he picturesquely figured the spirochaetes as shedding granules like "drops of water from a dog's tail."

In 1913 Balfour returned to London to found the Wellcome Bureau of Scientific Research, and to organize the nucleus of what afterwards became the Wellcome Museum of Medical Science. In that year, too, he undertook an extensive tour of South American countries and of the West Indies, upon which he published a valuable and well-illustrated report.

The outbreak of war found him in uniform again, first in France in 1915, and later as lieutenant-colonel, a member of the medical advisory committee in Mudros, Salonica, and Egypt. In 1917 the activities of this committee, of which he had then become the president, were moved to Mesopotamia, where he worked indefatigably for a year. Returning to England, he was later appointed scientific adviser to the Inspecting Surgeon General, B.E.F., East Africa, and after many arduous months spent in what is now Tanganyika Territory, and Uganda, he reached Egypt in the early part of 1918, and immediately undertook the reorganization of the health service of that country, being appointed president of the Public Health Commission. The value of his services to the Army and to the British cause during these strenuous years of

war is difficult to estimate. He did an enormous amount of good work in co-ordinating scientific effort, and in devising new methods of sanitation. He constituted himself the chief enemy of the house-fly, by pointing out the damage caused by "the filthy feet of faecal feeding flies"—a catch-phrase of his own. His last services during the world war were in Palestine, which he visited at the request of General Allenby, in order to report upon the antimalaria methods which proved to be so successful during the latter part of 1918. The beginning of 1919 found him at work at the Wellcome Bureau of Scientific Research, where he organized the museum with typical energy, originality, and enthusiasm. His life was enlivened at this period by visits, in 1921 to Mauritius, and in 1923 to Bermuda. As a result of these visits he issued several sanitary reports upon which action has been taken, and which have resulted in benefit to the health of the islands concerned.

The appointment of Balfour in 1923 to the directorship of the London School of Hygiene and Tropical Medicine met with general approval on all sides, for it was realized that a man with imagination, tact, and discretion had been secured, one of wide experience of men and affairs in many lands. For the last seven years his time and energy had been absorbed in organizing the new School. In order to aid him in this stupendous task, and to gain an insight into American educational methods, he first paid a visit to the United States, including the Rockefeller Institute. Returning to London he supervised and inspected almost every detail in the structure of the great new building, whose magnitude can only be realized by those who have seen it. The intensity of his labours at this time brought on a nervous breakdown in 1929, from which he appeared to recover. During recent years it had been felt by his friends that he could not well add to his already Herculean labours, so he was urged not to increase his activities, and on this account he was unable to deliver the FitzPatrick Lectures.

Of honours Balfour had quite rightly a good share. In 1907 he received the Imperial Ottoman Order of the Osmanieh of the 4th Class. He was created C.M.G. in 1912, C.B. in 1918, and K.C.M.G. in 1930. He was D.Sc. and LL.D. Edinburgh, LL.D. of Johns Hopkins and Rochester Universities, U.S.A., Fellow of the Royal Colleges of Physicians of London and Edinburgh, Cragg's Research Prizeman in Tropical Medicine, 1905, President of the Royal Society of Tropical Medicine and Hygiene, 1925-27, a member of the Colonial Advisory Medical and Sanitary and Research Committees, and of the Army Pathological Advisory Committee. He received the Mary Kingsley Medal of Liverpool in 1920.

Of his more permanent contributions to medical literature the following may be mentioned: *Public Health and Preventive Medicine*, 1902 (with C. J. Lewis); *Memoranda of Medical Diseases in Tropical and Sub-Tropical Areas*, which passed through two editions, 1916; *War against Tropical Disease*, 1920; (with Campenhout, Martin, and Bagshawe) *Reports to the Health Committee of the League of Nations on Tuberculosis and Sleeping Sickness in Equatorial Africa*, 1923; (with H. H. Scott) a volume for the British Empire Exhibition, *Health Problems of the Empire*, 1924. He also wrote the fine section on "Personal Hygiene in the Tropics and Minor Tropical Sanitation" in the first volume of Byam and Archibald's *Practice of Medicine in the Tropics*. He was also the author of innumerable articles and addresses on tropical medicine and public health subjects.

Early in his career Balfour achieved quite a considerable fame as a novelist, and thereby added to his somewhat slender stipend. Of his novels, the following may be mentioned: *By Stroke of Sword* (1897), *To Arms* (1898), *Vengeance is Mine* (1899), *Cashiered and other War Stories* (1902), and *The Golden Kingdom* (1903), the last of which is considered to be by far the most successful, and is founded upon his scientific knowledge of sleeping sickness. He was also known as an amateur actor of very considerable talent and originality. As a sportsman Andrew Balfour will always be remembered by the general public. He was noted as a boxer, and as a Rugby footballer of the first rank, playing for both Edinburgh and Cambridge, obtaining his "blue" at the latter university. He won his international cap for Scotland in 1896, and again in 1897. During recent years he took a great interest in the London Scottish Football Club, was on the selection committee of the Scottish Rugby Union, and, during the present season, was its president. In other branches of sport he held his own, and was an ardent big-game shot.

Of his personal attainments it may be said that Andrew Balfour will be missed as a "white man" in scientific, sporting, and Army circles. He had myriads of friends, and made no enemies; he was described by an old friend as a "rock of a man," handsome of mien and fine of figure. A staunch friend, modest to a fault, generous in thought and action, a popular speaker with a wealth of imagination and wit, he was verily a gentle and most gallant knight. As a raconteur he was well known, often "roaring like a bull" (as he himself put it) at his own jokes. Rarely, if ever, can devotion to his calling have been excelled. He undertook the Sisyphean labours of making reference for his private use of all the current literature on hygiene and tropical medicine in all languages of the world, working often far into the night, till he broke down.

Sir Andrew Balfour married in 1902, and leaves a widow and two sons, the elder of whom is studying for the medical profession. P. H. M-B.

Dr. WILLIAM HUNTER, C.B., writes: "The dearest man, the kindest friend, the most unvarying in doing courtesies" whom it has been my happiness to know; a man endowed with great gifts, of tireless energy, and unbounded enthusiasm in his life's work, now cut short when it was at its fullest maturity, crowned with the recognition it so richly deserved. Such are among the first thoughts personal to himself aroused by the loss which the whole profession has sustained in the death of Andrew Balfour. Among the qualities of his character which became well known to me during my association with him on war service in the Eastern areas of the Dardanelles, Salonica, Egypt, Palestine, and Mesopotamia, as one of my colleagues on the Advisory Committee of which I was president, there was none more pronounced than his intensely practical interest in all the clinical problems presented in his work. I always recall how keenly he would turn his thoughts and interest from camp matters to any suggestion of alleged remedies in current medical literature. When he himself "went down" to paratyphoid in the Dardanelles (at the same time as I "went down" to dysentery), he spent a temporary convalescence at home by writing an extremely helpful and instructive handbook on tropical diseases, full of hints regarding treatment. These practical qualities had been evidenced in his career from the very first in the great work of sanitation and prevention which he initiated at Khartum and continued in his later war services in Mesopotamia and East Africa. It was this aspect of his character, added to the more scientific interests with which he was inspired, that held out so fine a prospect of further service in his appointment as director of the London School of Hygiene and Tropical Medicine. He had a world-wide view of his whole subject, and his loss can only be fully appraised by his fellow workers in that branch of medicine.

ARCHIBALD LEITCH, M.D.

Director of the Cancer Hospital Research Institute; Professor of Experimental Pathology, University of London

The death of Professor Archibald Leitch on January 27th, at the early age of 53, was the result of an affection of the heart of some years' duration, which had rapidly become more serious in the last few months. He was a native of the Island of Bute, and was educated at Rothesay Academy, where he was prominent as an oarsman and sprinter. He liked to recall that in the interval between school and college, when he had no other means of seeing the world, he crossed the Atlantic in the capacity of cabin-boy. He entered as a student at the University of Glasgow, where he held the Duncan Bursary in arts and the Paterson Bursary in natural philosophy and mathematics, and gained the Black medal for physics and the Dobbie-Smith gold medal for original research in botany, while in later life he was awarded the Bellahouston gold medal for his research work. He was president of the University Liberal Club, and remained throughout life a wholly unrepentant Free Trader; he had many stories to tell of the methods of rectorial elections. He graduated in medicine in 1902. His connexion with the investigation of cancer began soon after qualification, when he was appointed house-surgeon at the Cancer Hospital, London. He went from there in 1905 to the Middlesex Hospital Cancer Research Laboratories, which at that time were very active in many new lines of investigation under a recently appointed chief, Dr. (now Professor) Lazarus-Barlow. He then spent some years in Dundee as director of the Caird Research Laboratory, where he carried out many experiments on immunization against inoculated tumours. He returned to the Cancer Hospital in 1912, when he was appointed pathologist; after the war he became director of the Research Institute, and there his best-known work on cancer was done. Soon after the outbreak of war he obtained a commission in the R.A.M.C., Territorial Force, serving in France with one of the field ambulances of the 58th Division, and later with the 63rd Casualty Clearing Station; finally he was the officer in charge of a mobile bacteriological laboratory in the Fifth Army area.

In 1922 Leitch demonstrated the cancer-producing power of shale oil, and thus showed where to seek for the cause of the cancer of the skin which is prevalent in cotton mule-spinners. In the succeeding years he showed that some petroleums are likewise carcinogenic. He found also experimentally that such cancers may arise after the application of the cancer-producing agent has ceased, and thus threw light upon those cases in man where an occupational cancer appears long after the work to which it is to be attributed has been given up. He was successful in repeating Kazama's experiments on the production of tumours in the gall-bladder of the guinea-pig by the insertion of foreign bodies. He carried out a good deal of work on the Rous tumour and on the tumours produced in fowls by the inoculation of tar and embryo pulp, and at the time of his last illness he was engaged in experiments in chemotherapy. Throughout his association with cancer research he was convinced that the most important thing was the investigation of every means of producing cancer which could be used experimentally, and thought that in the long run this would prove the surest means of gaining control of the disease.

His critical judgement was very acute, and was often applied with good effect to alleged discoveries. The value of his opinion in questions relating to cancer was due in large part to the fact that he was a good morbid anatomist and an exceptionally sound pathological histologist—qualifications which even nowadays are not out of date in cancer research. He was very well aware that every theory of cancer, however brilliant (for example, the view that a cancer arises from a single abnormal cell), must somehow make itself compatible with what one can see in any ordinary microscopical section. Leitch liked to acknowledge his debt to his teacher in botany, Professor Bower, for training in the difficult art of impartial observation, and in the discipline of not seeing things that are not there. His long experience of the difficulties of cancer research in the days before the experimental production of cancer in animals led him to express generous admiration for the work of Fibiger, and it was perhaps due in part to Leitch's advocacy that Fibiger, during the short remainder of his life, received fitting appreciation as a discoverer of the first rank.

Leitch was fond of relating stories, and had quite exceptional powers of mimicry. His presentation of what had occurred at a committee meeting was often extremely vivid, and contained a great deal of matter not to be found in the minutes. Anyone who had heard him enact a lecture by Lord Kelvin on the propagation of sound, illustrated by calculations not free from error upon a prodigiously wide blackboard, could never forget the humour of it. He worked for the British Empire Cancer Campaign in many capacities; he was a member of the Grand Council, of the Management Committee of the *Cancer Review*, and of the Investigation Committee, and served this last, and the Scientific Advisory Committee, as honorary secretary during the past year, until he was incapacitated by illness. He was an able member of any committee, and was apt to have an admirably clear grasp of the weak points of his opponent's case. He edited for the Campaign the valuable report of the International Conference on Cancer in London in July, 1928. He represented the Cancer Hospital at many international conferences, and found great enjoyment in these meetings. He was an enthusiastic member of the Leeuwenhoek Vereeniging, an international society of cancer research workers; the very name of this body was due to a timely

suggestion of his own, whereby certain differences of opinion about the priority of the French or of the German language were circumvented. He was a corresponding member of the Association française pour l'Étude du Cancer, and an honorary member of the Deutsches Zentralkomitee zur Erforschung und Bekämpfung der Krebskrankheit, and general secretary of the International Cancer Committee. He was consulted by authorities in many parts of the world about schemes of cancer research. Leitch was vice-president of the Section of Pathology when the British Medical Association held its annual meeting in Glasgow in 1922 and of the Section of Occupational Diseases at the Manchester meeting of 1929. He was also a member of the Research and Laboratory Workers' Subcommittee in 1919–21, and gave valued help to the *British Medical Journal* on many occasions, more particularly when the *Epitome* was revived after the war. He leaves a widow, a son who is studying medicine at Merton College, Oxford, and three daughters. In the spring of 1930 he was deeply distressed by the death of his colleague and close friend Dr. H. J. B. Fry. Anyone who knew Leitch well will have little doubt that the anxiety and sorrow arising from Fry's fatal illness may have played some part in hastening the last failure of his own strength.

Mr. W. ERNEST MILES, F.R.C.S., writes:

It is sad to know that Archibald Leitch henceforth will no longer be found in his accustomed place in the laboratory of the Cancer Hospital Research Institute, for death has claimed an earnest worker and a valued friend, whose wonderful personality now remains only as a memory. My association with Leitch began as far back as 1903, when he was appointed house-surgeon to the Cancer Hospital, and during the years that have since passed acquaintance ripened into lasting friendship. Although at first he fostered the idea of becoming a surgeon, the wealth of pathological material that lay at his hand attracted him to the study of the pathology of malignant disease. During the two years of his residence at the hospital his spare time was spent in the pathological laboratory and in the post-mortem room, thus laying the foundation of the brilliant achievements in cancer research which have earned for him the reputation that will endure as a permanent monument to his industry.

Archie Leitch, for he was so known to all his friends, was a man of unswerving loyalty and rectitude, and a tower of strength in council, whose expressed opinions were always the outcome of well-considered judgement. Endowed with an acutely critical mind, he accepted nothing that could not be proved by the demonstrable facts of pathology. He held strong views, and had the moral courage to express them strongly. "Fortiter in re" was his motto, particularly in debate, and woe to the adversary who had omitted to confirm his facts or was guilty of loose thinking or careless composition. His criticisms were in the main destructive, but nearly always right, for he was a ruthless dissector of ill-founded theories or imperfectly planned experiments. The Cancer Hospital, which he served so well, and its Research Institute, which by his genius and his industry he had placed in the foremost rank of centres for experimental research, have suffered an irreparable loss, and his colleagues there and I mourn an intimate and personal friend.

Dr. J. A. MURRAY, F.R.S., writes:

The death of Professor Leitch removes an interesting personality from the domain of cancer research in this country. His association with the subject comprised the whole of his scientific life in London, Dundee, and again in London at the Cancer Hospital. While in Dundee he made valuable contributions to the problems of immunity to transplantable tumours, and to the pathology of the curious multiple tumours of the rabbit's uterus. His most valuable work fell in the post-war period, and dealt with the problems of experimental carcinogenesis. Especially important were his demonstrations of the production of skin cancer in mice by arsenious acid, and the fact that the carcinogenic action of tar was not dependent on the arsenic content of the tar. Of fundamental importance was his observation that carcinoma might develop after cessation of tarring before proliferative changes had appeared. The late supervention of occupational cancer in individuals who had left the incriminated occupation for many years was thus clearly brought within the range of direct irritative causation and compensation. This practical application of his results, and the related problems of mule-spinners' cancer, occupied Leitch in later years to the exclusion of the further prosecution of the theoretical implications and avenues of development opened up by them.

Professor C. H. BROWNING, F.R.S., writes:

British pathology has suffered a great loss from the early death of Archibald Leitch, and those who knew him well realize that they are the poorer by a loyal and generous friend. In his work, as in all other affairs of life, he had a horror of shams, and the keen criticism to which he subjected his own efforts was turned also upon those of others. So it may come about that by some he will be remembered chiefly as a pertinacious and pungent controversialist. But when at times the expression of his objections appeared to be severe the aim was always directed upon what he conceived to be self-deception and the dangers to the cause of truth attendant thereon. His criticisms never bore the slightest trace of personal feeling. Leitch's work was inspired by an intense desire to lessen human suffering. Had circumstances been favourable at an early stage of his career surgery would have been the richer by an able exponent of its art and science. Thus when he turned to cancer research he firmly held in view the aid which advances in knowledge could afford, especially to the surgeon; for he strongly believed that the surgeon must long remain the most essential factor in dealing with cancer in the patient. From this aspect his share in the investigation of the paths of lymphatic spread of cancer will remain a contribution of the highest value. But not merely was he a specialist in cancer research; his interest in the problems of pathology and infection was universal, and equalled only by the soundness of his knowledge and judgement.

JOHN EDWARD GEMMELL, M.B., C.M.

Consulting Surgeon to the Hospital for Women, Shaw Street, and to the Liverpool Maternity Hospital.

By the death of Dr. J. E. Gemmell on January 24th, at the age of 67, Liverpool lost a faithful and notable son, and the members of the medical profession in the neighbourhood a greatly respected and dear friend and counsellor.

A native of Liverpool, Dr. Gemmell's early education was received at the Institute and College in that city, and after qualifying as L.S.A. in 1884 he proceeded to take the degree of M.B., C.M. at Edinburgh University in 1885. Scottish by descent, and with many Scottish traits in his outlook on and conduct of life, his interest in all things Scottish was marked. Throughout his active life he was a hard, conscientious worker, and though success came to him in no mean measure, he never allowed any diminution in meticulous attention to detail of all kinds. After graduation he acted as demonstrator in pathology and Holt tutorial scholar in physiology and

pathology at University College, Liverpool, and later was appointed honorary assistant surgeon to the Hospital for Women. Now fully embarked on his life-work as gynaecologist and obstetrician, he became lecturer in clinical gynaecology at the University, and full surgeon at the Maternity Hospital, as well as at the Hospital for Women. During his periods of service at these institutions he gave of his best to them in skilled work, particularly during the war. When, towards the close of his normal period of active service, the suggestion of hospital amalgamation arose, and he was requested to remain for an extra two years, he worked whole-heartedly in many directions towards advancing the scheme, and contributed in large measure to its success. In addition to contributions to medical journals, he frequently took part in discussions at the Liverpool Medical Institution and the North of England Obstetrical and Gynaecological Society. To the Liverpool Medical Institution, of which he was for two years president, he was a munificent donor, as well as being an enthusiastic supporter. He was twice elected chairman of the North of England Obstetrical and Gynaecological Society, and he was an examiner for the Central Midwives Board.

For long he was associated as surgeon with the Royal Naval Artillery Volunteers, and later the Royal Naval Volunteers. During the war he was sadly stricken. Of three sons on active service he lost two. Loyally proud and sad of the record, and irreparably wounded, he yet maintained much of that buoyancy and bonhomie which so characterized him throughout life. His was no narrow outlook on his specialty or on his profession; Gemmell's interest was in people, things, countries. Thus, in his latter years, as he neared the close of a full life, and saw his only remaining son, who had fought as a combatant in the war and had risen to command the Liverpool Scottish, ready to carry on in his stead, he loved to take long periods of travel in distant countries. To his widow and son whole-hearted sympathy is extended from a very wide circle of friends.

A. D. F.

Dr. G. F. RAWDON SMITH writes:

The death of Dr. John Gemmell has robbed the medical profession of Liverpool of one whom it will be impossible exactly to replace. As a clinical teacher few could surpass him, and I remember now hints he gave us as students in practical obstetrics—hints which cannot be found in any of the text-books. As a consultant one could always rely on an absolutely sound opinion, and as an operating surgeon he was hard to beat. At the end of the war some American doctors, who were making a round of British hospitals, told me that they came back to Liverpool to see Gemmell, whose technique, they considered, surpassed that of anyone in his particular line. As chairman of committee he was most delightful to serve under, for, while he had the faculty of getting the business through, he never annoyed anybody in his manner of doing so. His time of office as president of the Liverpool Medical Institution will always be a memorial to him, and his work on the committees of hospitals with which he was connected cannot well be overrated. In the theatre, where I worked with him for many years, I have never seen him ruffled in temper; to work with him was a genuine pleasure, and all his colleagues and nurses were really distressed when the time came for his retirement. But, after all, it was as a man that John Gemmell endeared himself to all of us. His never-failing help to anyone in trouble, his wise counsel, and his genial manner, formed a combination too rarely found. In addition to his professional work, his interest in music, the drama, and travel completed a delightful personality.

A surgical colleague sends the following tribute:

John Gemmell's whole career was marked by simplicity and vigour, and his temperament was in every way fitted to that career. He was a man whose advice was often sought by his medical friends, not only on matters immediately connected with his specialty, but on any general problems and difficulties which might beset them. He was looked upon as a wise and sane man, always ready to help, and for the last thirty years and more his assistance in every problem, individual and general, has been freely placed at the disposal of his contemporaries and of the younger generation. There are many who found him a tower of strength; herein lay his particular distinction. The new Maternity Hospital and the Women's Hospital now building are two public works which he did a great deal to create; his private benefactions were innumerable.

A very wide circle of friends, within the profession and outside, has heard with sorrow of the death, on January 24th, of Mr. WILLIAM BRADSHAW AINGER, F.R.C.S., at his home in Cadogan Place, S.W. He was born at Dunedin in 1878, received his early education at Christ's College, Christchurch, and left New Zealand to study medicine at St. Bartholomew's Hospital, qualifying with the diplomas M.R.C.S., L.R.C.P. in 1902. After a year's house-surgeoncy at the Metropolitan Hospital he made many voyages as medical officer to passenger ships on different lines, and then studied in Paris and in London for the Fellowship of the Royal College of Surgeons of England, which he obtained in 1910. For the next few years he practised in Sloane Street with steadily growing success, and held part-time posts as clinical assistant at St. Bartholomew's and other hospitals. On the outbreak of war he received a commission as Captain R.A.M.C. (T.F.), and went to France in the autumn of 1914, serving for many months as surgeon with the No. 2 Red Cross Hospital at Rouen. After a period of duty in London as medical officer to King Edward VII Hospital for Officers he returned to France early in 1918, and worked in base hospitals at Etaples until demobilization in 1919. Thenceforward his whole time and energies were devoted to general practice of a very exacting kind in Knightsbridge and the other districts around Hyde Park. The success Ainger achieved was in proportion to his character and ability. He was a highly accomplished all-round practitioner, full of resource, swift in reaching an opinion, and as prompt in action; a man who inspired confidence and trust. For some years past he had fought against ill-health with a courage so well concealed that only his intimates knew the effort it cost him to get through the day's task. An old friend writes: "Bill" Ainger was the most unselfish of men, with a rare gift of sympathy which endeared him to all his patients and colleagues. Of no one is it truer to say that he had a genius for friendship; he entered whole-heartedly into the lives of his friends, sharing their troubles and smoothing out their differences, with never a thought for his own advantage. He was a most delightful companion. The combination of quick wits and strong common sense with loyalty and loving kindness won him a place by itself in all our hearts.

We regret to announce the death of Dr. JAMES LAWSON of Dunecht, one of the oldest medical practitioners in Aberdeenshire. Dr. Lawson graduated M.A. in 1878, and M.B., C.M. in 1881, at the University of Aberdeen. At the time of his death he was in his seventy-third year, and had been in retirement only a few months. He practised for nearly half a century in the vicinity of his birthplace. His medical studies were made possible only by strenuous endeavour, for during several sessions he walked daily to Aberdeen, a distance of over six miles, and returned in the afternoon to take his share in the work of the farm before commencing his studies in the evening. His powerful physique and his intellectual

gifts enabled him to overcome all difficulties, and he retained to the end his habits of simple living and of hard work. By dint of early rising and constant reading he not only kept himself in an unusual way in touch with modern medical and general literature, but was throughout his life a keen student of natural science, and particularly of botany. His devotion to his work and to his library left him with little time or inclination for outside pursuits. He was a man of sterling character who did not make friendships lightly, but to those who knew him well he was a staunch companion. He gave freely of his skill and advice to his patients without thought of financial reward. He was laid to rest in the churchyard of Echt under the shadow of the hills he loved so well, and the large gathering of mourners bore evidence to the esteem and affection in which he was held by all classes of the community.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

E. G. Fearnsides Scholarship

The Vice-Chancellor gives notice that this scholarship, which is for clinical research on the organic diseases of the nervous system, is open to members of the University or of Girton College or Newnham College who are graduates or titular graduates in medicine, or to graduates or titular graduates in arts who have passed Part II of the Natural Sciences Tripos. (For conditions see *Ordinances*, p. 540.) Applications must be sent to the Registrary before June 20th, 1931.

UNIVERSITY OF LONDON

Sir George Newman, K.C.B., and Mr. Arthur Edmunds, senior surgeon to King's College Hospital, have been appointed Fellows of King's College.

The Julius Mickle Fellowship has been awarded to Dr. C. H. Andrewes for 1931 for his research work on viruses.

LONDON SCHOOL OF MEDICINE FOR WOMEN

Miss Elizabeth Bolton, M.D., B.S., has accepted the honorary office of Dean of the London (Royal Free Hospital) School of Medicine for Women, on the resignation of Lady Barrett.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A meeting of the Royal College of Physicians was held on January 29th, when the President, Sir John Rose Bradford, Bt., was in the chair.

Representation of People Bill

The College passed a resolution expressing strong disapproval of the proposal contained in the Representation of the People Bill to abolish university franchise and university representation.

Appointments

Dr. J. A. Arkwright was elected an examiner in tropical medicine and hygiene, and the President announced that the Censors' Board had appointed Dr. James S. Collier to deliver the FitzPatrick Lectures in November.

The following Fellows were appointed representatives of the College: Sir John Rose Bradford, at the centenary celebrations of the British Association for the Advancement of Science in September next; Dr. H. H. Dale, at the Faraday celebrations at the Royal Institution of Great Britain in September; Dr. F. G. Chandler, at the seventh annual conference of the National Association for the Prevention of Tuberculosis at Margate in June; Dr. S. Monckton Copeman, at the congress of the Royal Sanitary Institute at Glasgow in July; and Dr. J. L. Birley, at the second biennial conference of the National Council for Mental Hygiene, London, in May.

Membership

The following were elected Members of the College:

Gilbert Cleary Babington, M.D., Kenneth Vernon Bailey, *M.C.*, M.D., William George Barnard, L.R.C.P., Andrew Russell Buchanan, M.D., George Douglas Gordon Campbell, M.B., Frederick Russell Chisholm, M.D., George Alexander Davidson, M.D., Derek Ernest Denny-Brown, M.B., Carl Hercules Fouché, M.B., John Lewis Franklin, M.B., Mohammad Mohammad Gaafar, [illegible]phenson Hall, L.R.C.P., Percy Ellis [illegible] R.C.P., Sydney Walpole Hardwick, [illegible] Hoyle, M.B., Stanley George James, M.B., Florence Heath Johnson, M.B., Austin Braybrooke Kettle, M.B., Norman Murdoch Matheson, M.B., Louis Mirvish, M.B., William Eric Marcus Mitchell, *M.C.*, M.B., Geoffrey Charles Pether, M.B., Datla Satyanarayana Raju, M.B., George Harold Robertson, M.D., Stephen John Scurlock, *M.C.*, M.D., Gwladys Victoria Smallpeice, M.D., Laurence Alfred Howard Snowball, M.B., Edward Samuel Stern, L.R.C.P., Samuel Sappy Suzman, L.R.C.P., Percy Stanley Tomlinson, D.S.O., L.R.C.P., Ernest Rohan Williams, M.B.

Licences

Licences to practise physic were granted to the following:

J. E. Abell, I. S. Acres, F. P. Adams, †S. S. Ahluwalia, N. W. Alexander, S. Amir-ud-Din, A. T. Andreasen, Gwendolen E. Austin, H. B. Barker, C. C. Beresford, C. E. Bevan, B. N. Bhandari, K. Biden-Steele, E. T. Blacklee, J. F. E. Bloss, L. T. Bond, J. D. Bright-Richards, K. C. Buck, J. T. Cahill, H. Canwarden, A. B. Carter, †W. N. Chalmers, M. H. Churchill, A. R. Clarke, G. M. Conder, J. Diplomas

The following diplomas were granted, jointly with the Royal College of Surgeons:

PUBLIC HEALTH.—S. D. Ahuja, Mary E. Appleby, R. Behari, F. W. Bradley, E. L. Carter, Elizabeth Cooper, W. L. S. Cox, J. Fenton, A. Golombek, F. Grundy, M. L. Gulatee, W. Gunn, Josephine M. Howells, L. R. Kapur, Margaret S. Mackay, L. M. J. A. Pilot, S. T. Seccombe, W. E. Tyndall, K. K. Wood.

PSYCHOLOGICAL MEDICINE.—W. R. Ashby, E. P. Bovie, T. P. Curran, B. Das, J. B. Dedman, G. H. Fraser, B. K. Lal, W. Lambert, S. J. Laverty, T. W. Robbins, junr., T. G. Short, May I. Wallace.

LARYNGOLOGY AND OTOLOGY.—A. L. Bryant, E. J. G. Glass, A. S. Hatch, H. B. Lieberman, M. L. Poston, D. I. Rees, W. J. Roche, G. C. Snell, Nettie H. Stein, J. D. Wicht, R. N. Wilcox.

Lectures

Surgeon Captain S. F. Dudley, R.N., will deliver the Milroy Lectures on February 26th and March 3rd and 5th, at 5 p.m., on "Some lessons of the distribution of infectious disease in the Royal Navy"; Dr. Macdonald Critchley the Goulstonian Lectures on March 10th, 12th, and 17th, on "The neurology of old age"; and Sir William Willcox the Lumleian Lectures on March 19th, 24th, and 26th, on "Toxic jaundice."

CONJOINT BOARD IN SCOTLAND

The following candidates, out of eighty-one who entered, have been approved at the examination indicated, and have been granted the diploma of L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P. and S.Glas.:

J. L. Razdan, B. Meyerowitz, F. Nafi, M. J. Liebenberg, J. Cochran, H. W. C. Robertson, E. E. Smithers, A. R. Rasaiah, A. E. Carrol, T. W. Gregory, Wai-Ming Tso, J. C. Blok, C. L. Tessensohn, N. Shapiro, R. Morton, J. D. Blaine, A. A. MacDougall, H. Michaelson.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—G. C. Brown, W. G. Kingston, S. H. Thaler, S. M. R. Tuteur.

MEDICINE.—A. J. P. Coetzee, D. R. Rigg, R. Schauder.

FORENSIC MEDICINE, HYGIENE, AND INSANITY.—A. J. P. Coetzee, C. L. Ferguson, W. R. Packenham, D. R. Rigg.

MIDWIFERY.—G. C. Brown, A. E. Mathews, A. W. Toussaint.

Medical News

On the occasion of the tenth anniversary of the Polish Society of Oto-Laryngology Sir StClair Thomson was elected an Honorary Member.

A public meeting, under the auspices of the Aberdeen Division of the British Medical Association, will be held in the Cowdray Hall, Aberdeen, on Wednesday, February 11th, at 8.15 p.m., when Sir Robert Bolam will deliver an address on "The hospital and the doctor in a national medical service." Dr. Thomas Fraser will take the chair.

A special discussion on mental symptoms associated with brain tumours has been arranged for a joint meeting of the Sections of Neurology and Psychiatry of the Royal Society of Medicine to be held on Thursday, February 12th, at 8.30 p.m.

The next meeting of the Chelsea Clinical Society will be held at the Hotel Rembrandt, on Tuesday, February 17th, when Dr. W. Langdon Brown will open a discussion on the treatment of glandular deficiencies. Dinner at 7.30.

The annual dinner of the Glasgow and Aberdeen Universities, North-East of England Club, will be held on Thursday, February 12th, at 7 o'clock, at the Station Hotel, Newcastle-on-Tyne. Graduates of Glasgow and Aberdeen Universities will be welcomed, and tickets may be obtained from Dr. J. Y. T. Greig, Armstrong College, Newcastle-on-Tyne.

The annual general meeting of the Medical Officers of Schools' Association will be held at 11, Chandos Street, W.1, on Friday, February 20th, at 5 p.m. After the conclusion of business Dr. W. J. O'Donovan will read a paper on impetigo in day schools and public schools.

The Pharmaceutical Society of Great Britain will hold a conversazione at 17, Bloomsbury Square, W.C., on Tuesday, February 10th, from 7 to 10 p.m. The whole of the society's premises will be thrown open to visitors, and there will be exhibits in the museums, library and school, and in the research and pharmacological laboratories.

A joint meeting of the Manchester Medical Society and the Liverpool Medical Institution will be held in the Medical School of the University of Manchester, on March 5th, at 5 p.m. Mr. Geoffrey Jefferson will read a paper on the surgery of the pituitary body, Dr. H. T. Ashby will discuss the treatment of pulmonary tuberculosis in children by sanocrysin, and Mr. J. B. Macalpine will speak on some points in the diagnosis of ureteric stone. At a joint meeting of the Manchester Medical Society with the Pathological Society of Manchester, to take place on April 15th, Dr. Arthur J. Hall will give an address on epidemic encephalitis.

A meeting of the National Council for Mental Hygiene will be held at 11, Chandos Street, W., on Thursday, February 12th, at 5.15 p.m., under the chairmanship of Sir Squire Sprigge, when Mrs. Neville Rolfe will read a paper on modern marriage and its problems.

A meeting of the London Jewish Hospital Medical Society, Stepney Green, E., will be held on Thursday, February 12th, at 3.30 p.m. Mr. Somerville Hastings, F.R.C.S., M.P., will give an address on the trend of medical practice. Visitors will be welcomed.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 44. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1. The list of special courses arranged for 1931 is now available.

The following post-graduate courses will be held in Berlin during March and April, under the joint auspices of the Berlin University medical faculty and the German organization for international courses. From March 2nd to 7th there will be a series of lectures and demonstrations on various clinical problems viewed from the standpoint of the latest pathological and anatomical findings. A course in the practical aspects of diagnosis and therapeutics will continue from March 9th to 21st; this will be followed by a special series of demonstrations on radiodiagnosis and radiotherapy from March 22nd to 29th. A surgical course will be held from April 13th to 18th. Additional information about these courses may be obtained from the secretary of the international courses in Berlin, Kaiserin Friedrich Haus, Luisenplatz 2–4, Berlin, N.W.6.

As will be seen from an announcement in the advertisement columns, applications to participate in the Government grant for scientific investigations for 1931 must be sent to the Royal Society by March 31st. They must be made on forms to be obtained from the Clerk to the Government Grant Committee, Royal Society, Burlington House, London, W.1.

The National Opotherapeutic Institute of Pisa, founded by Professor Achille Sclavo, whose death was announced in the *Journal* of December 27th, 1930, will award an Achille Sclavo prize of 4,000 lire, and a consolation prize of 1,000 lire, for the best monograph on the present state of endocrinology, physiopathology, and clinical medicine. Competitors should send their work, which should be in print or typescript, to the director of the institute, Via Contesa Matilde 27, Pisa, by December 31st, 1931.

The centenary of the birth of François Sigismond Jaccoud, who died in 1913, was celebrated at a meeting of the Académie de Médecine on December 9th, 1930, when eulogies of him were delivered by the president, Professor Ménétrier, and the general secretary, Professor Achard. Jaccoud was professor of clinical medicine in the Paris faculty, author of a textbook of medicine, of which seven editions were published, of a remarkable work on the curability and treatment of pulmonary phthisis, and of clinical lectures delivered at the Pitie and Charité Hospitals, and translations of Graves's clinical lectures.

In the advertisement columns of the *Journal* this week will be found details of the regulations for the award of the second Garton prize and medal, which were instituted by the Grand Council of the British Empire Cancer Campaign in order to encourage investigations into the nature, causes, prevention, and treatment of cancer. The subject on which contributions are now invited relates to the biological effects and mode of action of radiations upon malignant and other cells. The award will be made early in 1934; the dissertations must be received by the honorary secretary of the British Empire Cancer Campaign not later than December 31st, 1933.

Under the will of the late Sir Otto Beit, £290,000 is left to his executors for distribution to charities and scientific institutions, including £50,000 to King Edward's Hospital Fund, £10,000 each to Guy's, the London, and St. George's Hospitals, £5,000 to the Homoeopathic Hospital, £2,500 each to the Children's Sanatorium at Holt and the Seaford Convalescent Home, £25,000 to the Imperial College of Science and Technology, £10,000 each to the Royal Society, the University of Cape Town, and the University of Witwatersrand, and £5,000 to the Strangeways Research Hospital at Cambridge.

Dr. Eva Louise Roberts, of the Inner Temple, was called to the Bar on January 26th.

Dr. Edwin Smith, coroner for the western district of London, has appointed Dr. W. H. L. McCarthy and Dr. F. T. Grey, barristers-at-law, to act as his deputy and assistant deputy respectively; and Mr. S. Ingleby Oddie, coroner for the central district, has appointed Mr. P. B. Skeels as his assistant deputy.

Dr. Demoor has been elected president of the Royal Academy of Medicine of Belgium for 1931.

The twenty-third Dutch Congress of Natural Science and Medicine will be held at Delft from April 7th to 9th.

A severe epidemic of diphtheria has recently occurred in Belgrade, causing the death of 104 children in two days.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Artificial Breast

"G.P." (London, N.W.) wishes to know of a really satisfactory form of artificial breast for the use of a young woman after amputation, and where it can be obtained.

Hystero-Epilepsy?

Dr. R. MACDONALD LADELL (Birmingham) writes: Dr. Crabtree describes in the *Journal* of January 24th (p. 163) a case in which psychological treatment is indicated. His patient apparently suffers from a self-induced hynotic trance, and treatment by analysis under hypnosis is possibly the correct line. One could then ascertain the real meaning of the manifestations, which are somewhat unusual and extremely interesting from a psychological standpoint.

Treatment of Obesity

Dr. B. A. M. HENDERSON (West Hartlepool) writes: In reply to "A. S.," I would suggest the treatment of a famous medical man recently commemorated in the *British Medical Journal* and make the patient literally "walk it off." She should take steady long walks of two hours or so without a pause, and at other times be kept "on the run," constantly hurrying about. This was probably her mode of life when she was quite slender, and there should be very little sitting about. She should take no sweets of any kind, no alcohol, no confectionery or puddings, and hardly any bread. Dry wheat or rye biscuits should take the place of bread. Meals should be as small as possible, and only three in the twenty-four hours. A fast day once or twice a week, with only tea and dry toast, would be a good plan.

Income Tax

Assessment on Partnership

"PARTNERSHIP" inquires how one member in a two-handed practice should return his earnings for super-tax purposes. For example, should he return his fraction (one-half) of the firm's assessment? The housing, car expenses, etc., are not identical for the two partners.

*** In such cases the income tax assessment is really the aggregate of the partners' liabilities, calculated by deducting their own expenses from their shares of the amounts credited to them out of the partnership account. The best method is to ask the inspector of taxes—assuming that he has been supplied with the detailed figures—to divide the assessment, and to check his division to see that due regard has been paid to the difference in car expenses, etc. If some such steps are not taken the result may, of course, be that too much surtax will be assessed on any partner liable to that tax.

LETTERS, NOTES, ETC.

Snake-bite in India

Mr. H. HARCOURT, I.C.S. (ret.), writes: In the second commission of the recent Assembly of the League of Nations the Indian delegate asked for the study of serums for use against snake-bite. The request was a very proper one. Between nineteen and twenty thousand persons die yearly in British India of snake-bite. How many are bitten and recover no one can say. Available statistics of fatal cases only are based on reports made to district magistrates through the police. These fatalities are unevenly distributed throughout India; Bihar, with a population of 34,000,000, having the highest yearly average of rather over 4,500. It is curious that the subject has never excited much interest either here or even in India. Our Indian brethren are disposed to accept the casualties in a needless spirit of submission. And the mischief occurs almost wholly in the hot weather, when visitors have disappeared from the scene, and Governments have departed to the hills. Moreover, high though the total figure is, it is scattered among half a million villages. And to a large extent the concentration of sufferers in centres of treatment is quite impossible. Time is the essence of any treatment that can hope to be successful, and travel along village paths in India is a slow business, especially at night, and it is at night that these cases mostly occur. I am aware that good work has been done in India by Lamb and others along the lines desired by the Indian delegate; but the fact that the mortality figures remain fairly constant suggests that much remains to be done. It is interesting to note how much more successfully the problem has been tackled in Brazil. In June, 1927, the *Times* published a special Brazil number in which it devoted over two columns to the work of the Butantan snake farm and to the serum there produced, and from there distributed throughout Brazil. It was noted that, whereas in the State of Sao Paulo snake-bite was formerly responsible for 3 out of every 1,000 deaths, it is now responsible for less than 1 per 1,000. No doubt India's problem is more difficult than that of Brazil. There is a greater variety of snakes in India, and many of them, unlike those in Brazil, are of the colubrine type, which kill more rapidly than the viperine. To get a single serum applicable to all types of snake poison is likely to prove very difficult, and yet, without that, efficient treatment is hardly practicable. It might be possible through existing dispensaries and perhaps through village notables of intelligence to bring a single serum within prompt reach of victims in selected areas at least; but more than that is too much to expect. More often than not the particular type of snake that has offended is not known, and for any but experts to make a selection among different serums is out of the question.

The Umbilicus as a Source of Infection

Dr. G. G. COOPER (London, W.C.) writes: In the report of the Department of Health for Scotland on Puerperal Fever (*British Medical Journal*, January 31st, p. 191) I notice no reference is made to the cleansing and disinfection of the umbilicus as prophylactic treatment. I give two examples in my experience: (1) In 1923 I acted as locumtenent in a county hospital, and, in the case of a woman who had had an abdominal operation, the wound became septic. I had the umbilicus, which was deep and unclean, properly cleaned out and disinfected with tincture of iodine, and the operation wound soon cleared up. (2) I treated (while acting as medical officer in the French Foreign Legion) an officer who had developed an inflamed oedematous swelling round the umbilicus. I applied hot fomentations at regular intervals. A plug (1/2 in. to 3/4 in. long) of evil-smelling concretion came away from the umbilicus, and the condition returned to normal in a few days. I asked the officer if he had ever cleaned out the umbilicus, and he said he had never thought of it. This umbilical "plug" no doubt contained bacteria of various kinds, and perhaps had been developing during his whole lifetime. The inference seems obvious. Surgical technique is essential in conducting a confinement. We must not forget to clean out thoroughly and disinfect, at intervals during the pregnancy, the umbilicus, be it deep or shallow.

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 55, 56, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52, 53, and 54.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 43.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

120 Unusual Cases of Priapism

M. HUHNER (*Med. Journ. and Record*, December 3rd, 1930, p. 521) records six unusual cases of priapism in which the common causes were absent, there being no symptoms of venereal disease, traumatism, leukaemia, alcoholism, spinal disease, or cerebral neoplasm. All the cases had persisted for many years in spite of various treatments, but in two instances good results followed epidural injections. The first patient remained well for eleven years after two epidural injections of 60 c.cm. of normal saline solution with intervals of twenty days between each. During these years he was able to indulge in normal coitus, and his wife gave birth to a healthy child. The symptoms then returned, but he remained quite free after another epidural injection. In the second case the symptoms had existed for eleven years, but ceased immediately after an epidural injection of novocain in 60 c.cm. of saline solution, followed a week later by another injection containing novocain 10 c.cm. in 80 c.cm. of saline solution. The author attributes the improvement directly to the epidural injections.

121 Convulsions in Disseminated Sclerosis

C. B. RICH (*Canadian Med. Assoc. Journ.*, December, 1930, p. 820) reports a case of a severe convulsive attack in a married woman, aged 26, in whom signs of disseminated sclerosis had previously been detected. The patient was very pale and foamed at the mouth; there were spasmodic contractions of the limbs, face, and eyelids, more marked on the left side. The corneal reflexes were absent. The convulsions were controlled with difficulty by chloroform and morphine, leaving the patient deeply comatose, with very slow, shallow respirations. She was irrational during the next few days, and had no control over the urine or faeces. A week later she had regained control, and could speak rationally, but the speech was "scanning," and there was a syndrome of nystagmus, intention tremor, absence of the left biceps jerk, loss of abdominal reflexes, indefinite plantar response, and definite weakness in the right leg. Six weeks later all the reflexes had returned; the nystagmus and the intention tremor were hardly noticeable, and the patient walked unsupported, though with a slight limp. The Wassermann reactions of the blood and spinal fluid were negative; the colloidal gold reaction was 4555541000, and the globulin reaction (Pandy) was positive. Rich comments on the rarity of such convulsions in disseminated sclerosis, and suggests that in the delicate, highly strung, and probably unstable nervous system the interaction of nerve cells in some section was interrupted, causing a slight trophic disturbance, and a consequent vicious circle.

122 A Rubella Epidemic

M. O. BELSON (*New England Journ. of Med.*, November 27th, 1930, p. 1076) states that, during the first five months of 1930, 118 cases of rubella were reported from Charlestown, a section of the city of Boston, as compared with only one case during the whole of 1929. The characteristic features of the epidemic were as follows. It was remarkably mild. There was an almost complete absence of catarrhal symptoms preceding the eruption. In 35 out of 36 cases seen by Belson the eruption was the first symptom, and was not accompanied by itching or followed by desquamation. The eruption was most pronounced on the extremities and disappeared within twenty-four to seventy-two hours. In four cases a rash was seen on the palate. Enlargement of the posterior cervical glands was present in every case. The temperature was normal in 60 per cent., and in the remainder the rise of temperature ranged from 0.2° to 1° F., with one exception, in which it rose to 100° F. There were no complications.

123 Uraemic Meningitis

E. BOEGNER (*Thèse de Paris*, 1930, No. 317) maintains that meningeal reactions are more frequent in the course of uraemia than was formerly supposed. They are often absolutely latent, and systematic lumbar puncture in every case of nervous uraemia is required in order to detect them. The clinical phenomena are apt to vary considerably; in some cases the meningitis is discovered only by lumbar puncture, while in others the symptoms are definite and resemble those of the acute type. They may either supervene as a complication of nephritis, or appear at the same time as the renal symptoms. Their pathogenesis has been a matter of dispute. By some they have been regarded as exclusively toxic, and by others as infective in nature, but in many cases both causes are probably responsible, anatomical lesions of the meninges in chronic nephritis favouring the localization of intoxication or infection of the nervous system. A toxic origin for the meningeal symptoms should not be admitted until a complete cytological, bacteriological, and clinical examination has been made of the cerebro-spinal fluid.

Surgery

124 Cancer Developing in Burn Scars

N. TREVES and G. T. PACK (*Surg., Gynécol. and Obstet.*, December, 1930, p. 749) record a study of 28 cases of carcinoma developing in burn scars, all of which fulfilled Ewing's postulates. Malignant degeneration of scars is due to the surface extent and depth of the burn; the nature of the exciting agent, its capacity for heat absorption, and degree of temperature with the duration of contact are also factors. These tumours may be divided into acute wound and chronic scar cancers; the former develop within a year, and are more common in older subjects with atrophic, keratotic skins. The age of the scar is a more important factor than that of the individual. This history of scar cancer conforms to the general histogenesis of epitheliomata; this point is discussed in detail. These neoplasms appear in those parts of the head and face, and of the extremities most subject to burns. The authors have noted that many developed in regions where ordinary epitheliomata are infrequent—namely, the arm, elbow, groin, and popliteal space. Scar cancers on the head and face are the more serious since a radical operation is precluded. Irradiation, especially with heavily filtered radium at a distance, should be the first treatment; if this is not available, a wide local excision or cauterization may suffice. Curetting is inadvisable. The extent of an operation, if necessary, will depend on the location and extent of the lesion. Local excision of well-developed scar cancers is unsuccessful and dangerous. As a prophylactic measure, the adequate treatment of burns (early skin-grafting and radical excision of the scar) is emphasized.

125 Primary Tumours of the Heart

R. LERICHE and R. BAUER (*Arch. des Mal. du Cœur*, October, 1930, p. 645) describe a case of primary new growth of the heart and review the literature. These neoplasms are very rare, and many recorded cases have probably been instances of secondary tumours or of organized pedunculated thrombi. According to their site of origin, cardiac growths may be classified as valvular, intracardiac, and mural. The valve most frequently affected is the tricuspid, the growths being fibromata or myxomata. Intracardiac neoplasms are usually attached to the wall of the left auricle, and may be pedunculated or sessile; ultimately they may fill the cavity completely. Histologically they resemble the valvular growths. Neoplasms in the myocardium vary considerably in their size

and situation, but most often involve the left auricle. They are always solitary, but metastases may be observed in the neighbouring muscle; when they are large the great vessels or the valves may be interfered with, while interruption of the bundle of His has been observed from this cause. These tumours are generally sarcomata or rhabdomyomata. Clinically, valvular neoplasms may give signs of interference with the functions of the affected valve, while a growth in one of the chambers of the heart or in its wall may cause no symptoms or signs. Dyspnoea, intrathoracic pain, and haemorrhagic pleural effusion are the manifestations that have been most frequently observed. In the author's case a woman, aged 53, complained of dry cough and pain in the right side of the chest. There was dullness over the right side, but no significant signs were found in the heart. Radioscopy showed a dense rounded shadow corresponding to the area of dullness, and calcified at its upper border, which extended downward from the level of the second rib. Operation was undertaken for a dermoid cyst, but at necropsy a sarcoma was found originating in the right auricle and involving about two-thirds of the heart.

126 Trauma and Appendicitis

F. EICKEN (*Zentralbl. f. Chir.*, December 13th, 1930, p. 3095), who records an illustrative case, agrees with Lutz, who only admits that appendicitis is traumatic when traumatic changes are found at the operation, such as laceration of the serous membrane or haemorrhage into the layers of the appendix, or at least in the immediate vicinity. Eicken also requires that there should be undoubted microscopical evidence of an external injury. If such conditions are fulfilled the number of cases of traumatic appendicitis must be extraordinarily small. Sprengel, indeed, maintains that there is no connexion between trauma and appendicitis. Eicken's patient was a man, aged 27, who after hitting the right side of the abdomen against a gymnasium pole developed symptoms of appendicitis. On operation a small haematoma was found in the rectus sheath, but there was no peritoneal exudation, and the appendix was normal. Recovery was uneventful.

Therapeutics

127 Milk Injections in Erysipelas

For the local treatment of facial erysipelas, J. CHALIER (*Journ. de Méd. de Lyon*, December 5th, 1930, p. 713) employs only moist alcohol dressings, care being taken to protect the eyes. For general treatment, antistreptococcal serum has undoubtedly given good results, but Chalier strongly advocates the use of injections of milk, basing his opinion on the results obtained in over 1,000 cases. There followed a lowering of the temperature and a marked improvement in the general symptoms, especially in the nervous signs and delirium. The local effect is equally striking, and in many cases a distinct amelioration is noted after the first injection. The first doses are the most active; if these produce no effect, subsequent injections will probably prove useless. In favourable cases cure is obtained in two to four days; the average duration of the disease, however, is six days. Early treatment is of great importance. If injections are begun on the first day, the disease rarely lasts more than four days; if they are postponed to the fourth or sixth day, the treatment is of slight benefit. This method is said to be of great value in preventing the occurrence of exacerbations, and in forestalling or minimizing suppuration. Chalier remarks, however, that when the limbs are affected the results have been less favourable. A few cures have been obtained in erysipelas of the newborn, an almost invariably fatal malady. He uses filtered milk, boiled in a water bath for about twenty minutes. The adult dose is 10 c.cm., and this is given daily; three injections usually suffice, four being rarely needed. In children the dose ranges, according to age, from 2 to 5 c.cm.; in the newborn 0.5 to 1.5 c.cm. are given. The injections may be subcutaneous or intramuscular, the former being preferable. They cause local tenderness and redness, which readily yield to hot, moist applications. A transient, slight rise of temperature usually ensues, and occasionally headache, nausea, and lassitude. No severe effects such as anaphylactic shock have been observed. Contraindications are tuberculosis and cachectic states, uncompensated cardiopathies, nephritis, and alcoholic hepatitis. Well-compensated cardiac valvular disease and the albuminuria of erysipelas are not contraindications. Pulmonary complications are said to benefit from the injections.

128 Treatment of Peptic Ulcer

J. MEYER and L. B. KARTOON (*Arch. Int. Med.*, November, 1930, p. 768) investigated the effects of intravenous injections of foreign protein upon peptic ulcer in eleven patients in whom the clinical diagnosis was arrived at from an analysis of the history, symptoms, and such physical signs as localized tenderness, positive radiograms, and analyses of the gastric content and stools. Except for meat, the patients were on general hard diet and were allowed to be up. In addition to a routine Ewald test meal, a control fractional gastric analysis was made in the case of each patient, and on the following day an intravenous foreign protein injection of from 500 to 800 million gonococcus or typhoid vaccine was given. Five or six injections of the same doses were given at intervals of from five to seven days if the initial reaction was severe, but, if mild, the doses were increased to 1,000 million, 1,500 million, and up to 2,400 million. From twenty-four to forty-eight hours after each injection fractional gastric analyses and *x*-ray examinations were made before the first and after the last injections, with analyses of the stools throughout the whole observations. The gastric acidity was decreased in five patients, unchanged in four, and increased in one. The relief from pain accompanying treatment appeared to be independent of changes in acidity. The authors believe this to be due to the diminution in gastric tonus and contractions which followed the injections, and they think that the increased vascularity in the stomach and capillary bed near the ulcer is the important factor in such relief. They consider that the rhythmic pain in ulcer is due to rhythmic variations in the vascular bed in and around the ulcer, associated with digestive peristaltic activity. They add that, from the point of view of treatment for peptic ulcer, such non-specific protein can only be regarded as an adjunct to other methods.

129 M. LOEPER and M. DEBRAY (*Bull. Soc. de Thér.*, October, 1930, p. 232) record 17 cases of peptic ulcer, consisting of 2 ulcers of the lesser curvature, 7 pyloro-duodenal ulcers, 7 purely duodenal ulcers, and one case of periduodenitis, treated by subcutaneous injections of pepsin (0.1 gram) combined with sodium benzoate. In almost every instance the pain and vomiting ceased between the fourth and seventh injections. Radiological examination performed ten days after the termination of a series of injections showed a cessation of the spasm, improvement in the passage of food from the stomach to the duodenum, and a diminution of hyperkinesis. Two other patients, suffering from cancer of the stomach and cancer of the pancreas respectively, derived scarcely any benefit from this treatment, which is an example of combined protein and endocrine therapy.

130 Diet in Catarrhal Jaundice

P. CHEVALIER (*Bull. Soc. de Thér.*, November 12th, 1930, p. 268) deprecates a milk diet in catarrhal jaundice, but recommends that as soon as the stage of fever and gastric intolerance has passed, and the patient has regained his appetite, he should receive underdone meat such as roast beef or ham, accompanied by vegetables and fruit (cooked or raw). Bread and alcoholic drinks should be forbidden, but water should be given freely. A meat diet, while having no action on the jaundice itself, considerably improves the general condition, so that the patient recovers his health before the jaundice disappears.

Radiology and Electrology

131 Radiological Diagnosis of Scirrhous Gastric Cancer

L. TURANO (*Il Policlinico*, Sez. Med., October 1st, 1930, p. 469) reports six cases of gastric disease illustrating points in the radiological diagnosis of scirrhous cancer. The most suggestive signs of this condition are a small high stomach which is sometimes funnel-shaped, retention of food in the supracardial portion of the oesophagus, very rapid emptying of the stomach and filling of the duodenum and small intestine, and the absence of peristalsis. The patients are usually of advanced age, with slow onset of symptoms; pain, wasting, anorexia, feeling of emptiness in the stomach, and constipation are the most common. As a rule, palpitation of the stomach reveals nothing abnormal. In all these cases the radiological findings must be correlated with the clinical history and symptoms. In the differential diagnosis the other possibilities include gastric syphilis, plastic linitis, tuberculosis, contraction due to corrosive poisoning, and spasm. Special attention is paid by Turano to gastric syphilis, and reference is made to 87 cases collected from the Mayo Clinic. Three main types of gastric scirrhus are described—prepyloric, median, and total—corresponding to the different parts of the stomach affected. The author's case was of the second type, in a man aged 35. The operation revealed diffuse infiltration of the stomach but no sign of ulcer, and nothing more was done. Six months later the patient reported himself as being very well; he had put on 10 kilos in weight.

132 Encephalography in Fixed Lesions of the Brain

B. CROTHERS, E. C. VOGT, and R. C. ELEY (*Amer. Journ. Dis. Child.*, August, 1930, p. 227) consider that encephalography—the removal of cerebro-spinal fluid and its replacement by air—is a justifiable procedure for topical diagnosis and prognosis in cases where trauma or infection of the nervous system has resulted in cerebral damage. Reaction is the rule. During the injection, pallor, sweating, and vomiting are common, and rather alarming collapse is not rare. Pyrexia, with stiffness of the neck and a positive Kernig sign, suggesting meningeal irritation, begin a few hours afterwards, and last in some cases for several days. The authors have had only one death, and think that there is no likelihood of the symptoms being made worse. An absolute contraindication is increase of the intracranial pressure. The authors favour the ordinary lumbar puncture route, with the child sitting up; frequently repeated small doses of morphine until extreme drowsiness supervenes, followed by careful local anaesthesia, is probably the best preparation. They use one needle with Ayer's manometer and a three-way stopcock. The pressure is observed immediately after the introduction of the needle, and at intervals during the whole procedure; it is kept throughout at a lower level than at the beginning, and left at 100 mm. of fluid or lower. The fluid is allowed to drain slowly until 5 c.cm. have been withdrawn; 5 c.cm. of air are then introduced gently from a glass syringe. The pressure is checked and the process repeated; varying amounts of air, 20 c.cm. to 50 c.cm., are needed. The child usually remains quiet with a reasonably steady pulse and good colour, but pallor, irregular respiration, profuse sweating, and vomiting are not unusual, and give rise to some anxiety. For radiography the authors use an ordinary Potter-Bucky diaphragm with a horizontal table. With the patient in the prone position, they take right and left lateral stereoscopic films, shifting lengthwise to the patient at a distance of 25 inches (63.5 cm.). The patient is then placed on the back for the antero-posterior view. The head is turned from side to side, beginning with an angle of about 60 degrees, but gradually diminishing the arc till the face is directly up; this equalizes the remaining fluid and air in the ventricles. A single straight antero-posterior exposure is then made. After this the patient is turned face downwards, and a postero-anterior film is taken which outlines the posterior horns. The authors classify the film showing unusual distribution of air into four groups: (1) reasonably symmetrical dilatation of the ventricles—generally due to a deficiency of brain tissue; (2) marked asymmetry of ventricles, presumably from unilateral atrophy (the displacement of the intracranial contents is towards rather than away from the enlarged ventricle—a vital point in cases of tumour); (3) evidence suggesting deepened subarachnoid spaces dependent on cortical atrophy; and (4) absence of air in the ventricles—due to some unknown factor or to faulty technique.

133 Radiation Treatment of Polycythaemia Vera

G. T. PACK and Ll. F. CRAVER (*Amer. Journ. Med. Sci.*, November, 1930, p. 609) state that in polycythaemia with splenomegaly (originally described by Vaquez) irradiation is pre-eminently the mode of treatment—a view based on the character of the pathological process. The disease seems to be due to chronic overproduction of the erythrocytes, rather than to their delayed destruction or prolongation of life. The stimulus or cause of this condition is unknown, but its chief seat of action is the bone marrow, in which there is increased erythroblastic activity; this hyperblastic bone marrow is radio-sensitive. Erythraemia is analogous to myelogenous leukaemia, in which disease irradiation is the most satisfactory treatment. Both maladies occur during the same age periods, pursue the same chronic fatal course, and in each certain transitional forms exist. The authors believe that physical agents (radium and *x* rays) are superior to chemical ones in treating diseases characterized by excessive activity of bone marrow, the results, though temporary, being of longer duration. Since the spleen must be intact and functional, splenectomy is contraindicated in erythraemia. Venesection affords symptomatic relief, but may possibly stimulate the marrow dangerously to increased activity. Treatment must be directed to the bone marrow rather than the spleen, and sufficient irradiation must be given to inhibit or depress, but not destroy, erythropoiesis; the dosage depends on the severity of the illness. Both short and long bones are treated, the latter receiving most attention, especially if painful. No treatment is given to the head (to avoid alopecia) or to the pelvic bones in young women and men (to avoid damaging the gonads). Exactness in dosage is essential, and three to six exposures are given weekly. Sometimes three series are necessary, and these may be given at intervals of three to six months, depending on the response to treatment. Irradiation in polycythaemia does not cause the toxaemia which frequently follows its use in myelogenous leukaemia. The plethora is relieved, the general health improved, and life is prolonged by radiotherapy, but this measure is not capable of preventing a fatal termination. Four illustrative cases are recorded.

Obstetrics and Gynaecology

134 Early Diagnosis of Uterine Carcinoma

T. HEYNEMANN (*Med. Welt*, October 25th, 1930, p. 1541) urges full investigation of every case of abnormal uterine haemorrhage lest palliative treatment preclude the early diagnosis of cancer. Examination of the cervix should include inspection, since if the tumour is already palpable the condition is no longer limited to the uterus. Destruction of tissue and ulceration are practically diagnostic of carcinoma; erosion and swelling appear earlier, but may be due to other causes. Any destruction of tissue, swelling, tumour formation, or localized increase in vascularity should be investigated histologically. If on pressure with a sound any such suspicious area breaks down it should be considered malignant; if not, the diagnosis is doubtful. Leucoplakia is often a precursor of carcinoma. Diagnosis of early carcinoma of the cervical canal is difficult, since the only sign apart from haemorrhage may be swelling of the os. Carcinoma of the body is more favourable in respect of diagnosis and treatment; pain is an early symptom, but haemorrhage may be late. Any obstinate discharge in an elderly woman is suspicious, as is also irregular haemorrhage after the menopause where no cause can be found in the cervix. The necessary curettage in such cases must not be delayed.

135 Suppuration in Ovarian Cysts

V. RICHE and G. FAYOT (*Paris Méd.*, December 20th, 1930, p. 545) discuss the etiology, symptomatology, and treatment of suppurating ovarian cysts. Haematogenous infection is held to be very rare, except in the case of typhoid and paratyphoid fever. In 2 out of 7 cases treated by the authors the intestine was undoubtedly the primary cause of the infection, both cysts being intimately related to suppuration of the appendix. In 3 other cases the uterus was the infecting agency, and in the 2 remaining cases no cause was definitely determinable, though intestinal adhesions were discovered at the operations. The clinical history always begins with the onset of suppuration; in 6 out of the 7 cases the existence of any tumour was unsuspected until infection supervened. The condition was acute in 5 cases, pain, pyrexia, and signs of a peritoneal reaction being prominent manifestations. In the two chronic cases the onset was insidious, there being little or no pain, and very little constitutional disturbance. The authors commend the operative procedure of Mikulicz—extirpation in one stage, with abdominal drainage.

136 Chorion-Epithelioma without External Haemorrhage

D. v. RAISZ (*Zentralbl. f. Gynäk.*, November 15th, 1930, p. 2887) has found records of only four cases of chorion-epithelioma without utero-vaginal bleeding. He describes the case of a woman, aged 34, whose second pregnancy terminated spontaneously in the expulsion of a hydatidiform mole at four and a half months. Two years later three curettings were performed on account of irregular haemorrhage, but the microscopical findings were negative. More than two years of amenorrhoea followed. Sudden onset of abdominal pain, succeeded by rigors, and the discovery of a pelvic tumour, led to a diagnosis of internal haemorrhage from a ruptured ectopic gestation, with suppuration of the pelvic haematoma. An operation was deferred on account of the patient's poor condition and of the appearance of a purulent vaginal discharge, but was judged necessary seventeen days later, when it was found that a large chorion-epithelioma of the uterus had perforated and extended to the bladder. The amenorrhoea is explained as being due to the repeated curettings and to the fact that the chorion-epithelioma was originally intramural. The true pathology of the case was suspected, shortly before the operation, from the finding of a positive Zondek-Aschheim reaction in the urine. The case presents further evidence of the value of Aschheim's suggestion that this test should be performed at regular intervals in those patients who have given birth to a hydatidiform mole ; it is then likely to show the earliest sign of chorion-epithelioma.

Pathology

137 Haemolytic Anaemias

C. CASANO (*Arch. Path. e Clin. Med.*, November, 1930, p. 5), believing that many of the different pathological pictures of haemolytic anaemias represent transitional forms, and should not be regarded as clinical entities, has attempted to show their mutual relations. He describes in detail the clinical histories of twelve cases. The author considers that the haemolytic factor is a common denominator of an extensive group of morbid states which comprises haemolytic icterus, hypertrophic hepatitis with splenomegaly, Banti's disease, splenic anaemia, and pernicious anaemia; this group can be classed into subgroups according to the nature and degree of the excessive haemolysis occurring in these conditions. Pernicious anaemia (Biermer), which is primarily an affection of the bone marrow with an excessive destruction of constitutionally imperfect red cells, is to be distinguished from the other haemolytic anaemias and pernicious anaemia splenomegaly (Strümpell), where the spleen takes a more active share in the production of haemolysin and red cell destruction. Banti's disease, and splenic anaemia resulting from inhibition of erythropoiesis by the spleen, are regarded as a separate group. In explaining the etiological affinities of these syndromes, the abnormal activities of the splenic and extrasplenic reticulocytic systems are regarded as associated with constitutional debility.

138 Multiplicity of Antigens in B. anthracis

According to A. SORDELLI and V. DEULOFEU (*C. R. Soc. de Biologie*, December 12th, 1930, p. 721) agar cultures of *B. anthracis* contain a precipitinogen which is soluble in distilled water or saline solution, and which is precipitated by alcohol-sodium acetate. When purified by repeated precipitation it reacts like a carbohydrate, failing to give the biuret or Millon reaction, but yielding an intense Molisch reaction, and actively reducing copper salts after preliminary hydrolysis with weak sulphuric acid. Even when diluted 1 in 1,000,000 it gives a precipitin reaction with an anti-anthrax serum. Agar cultures of *B. anthracis* likewise contain a substance capable of fixing complement and soluble in distilled water or saline solution; it does not appear to be identical with the precipitinogen. The complement-fixing antigen is largely destroyed by treatment with acetone or with 96 per cent. alcohol, while the precipitating antigen is not markedly affected. The two antigens can be separated by saturating an extract of anthrax bacilli with ammonium sulphate; the precipitate, which is soluble in water, fixes complement, but has no precipitating power. On the other hand, repeated treatment of an extract of the bacilli with alcohol-sodium acetate yields a body which, as described above, has a high precipitating power, but which is unable to fix complement. The authors conclude, therefore, that there are at least two different antigens in *B. anthracis*.

139 Silicosis and Tuberculosis

In a discussion of the nature and sequels of silicosis T. H. BELT (*Canadian Med. Assoc. Journ.*, December, 1930, p. 802) expresses the view that it is not the fibrosis of silicotic lungs which favours the tuberculous infection, but simply the presence of siliceous dust. He records three cases in the early stages of silicosis, with much dust in the lungs but no appreciable degree of fibrosis; each of the three patients died with massive bilateral caseous tuberculous involvement. Silica does not stimulate the growth *in vitro* of tubercle bacilli, but *in vivo* its action in promoting a fatal type of tuberculosis is admitted. It has been suggested that the silica may surround the bacilli with a sheath of devitalized tissue, into which phagocytes do not readily penetrate, or that it may stimulate bacillary reproduction. Others have thought that by virtue of its colloidal properties silica absorbs antibodies, and so protects the organisms. Belt remarks that this dust, being ubiquitous, may perhaps play some part in bringing about tuberculous infection in ordinary life.

140 Experimental Uraemia

A. G. CHIARIELLO (*Rinascenza Medica*, October 1st, 1930, p. 471) has produced uraemia in dogs by simultaneous bilateral ligature of the ureters. Before the operation two determinations of the electrolytic equilibrium of the blood were made on separate days, and these were repeated every day after the operation, which was followed by rapid impairment of the general condition, with prostration, disinclination for food, and in some cases, a few hours before death, by short tonic and clonic convulsions. The animals survived rather over 48 hours, dying usually between the second and third days. The determination of calcium, magnesium, and sodium was made by the micro-method of Conderelli; chlorine by Bang's method modified by Conderelli; inorganic phosphorus by the method of Bell and Doisy; and potassium by the method of Kramer and Disdal modified by Conderelli. The results showed that there is no constant change in the amounts of chlorine, phosphorus, or magnesium, but that there is a slight decrease of calcium, an increase of sodium, and a remarkable increase of potassium. The author considers that the uraemic syndrome following the operation is not explained by these alterations of electrolytic equilibrium, and that the "hyperpotassiemie" is to be regarded as a reaction of the organism common to all toxic conditions rather than a specific fact of the uraemic syndrome.

What shall I prescribe?

WHEN CONFRONTED WITH A DIFFICULT CASE OF OSTEO OR RHEUMATOID-ARTHRITIS IT IS INDEED COMFORTING TO KNOW THAT QUICK AND LASTING RELIEF CAN BE OBTAINED FROM THE ADMINISTRATION OF ELIX. FORMASAL AND TAB. ARTHRITONE.

[THE POPULARITY OF THESE PREPARATIONS IN RHEUMATIC CONDITIONS IS DUE SOLELY TO THE GOOD RESULTS OBTAINED.]

PRACTITIONERS HAVE TAKEN THE TROUBLE TO WRITE AND TELL US OF THE WONDERFUL EFFECTS THAT THESE PREPARATIONS HAVE IN CASES WHERE ALL OTHER FORMS OF MEDICATION HAVE BEEN OF NO AVAIL.

"STERULES"

(Registered Trade Mark)

FOR

Hypodermic, Intramuscular, Intravenous, and other forms of Injection.

(Care should be taken to prevent confusion as to use in each instance)

ARSENIC AND IRON *(intram.), successful in the treatment of anæmia*, Nos. 1 and 2 ... ... Box of 10 3 6
Either form with Strychnine, 1/60 grain .. ... Box of 10 4 0

CALCIUM CHLORIDE, *hæmostatic and in calcium therapy.* 1 grain in 1 c c. and other strengths ... ... Box of 10 4 6

EMETINE HCl. *(hypod., intrav. or intram.).* ¼ *and* ⅓ grain, 4/6; ½ gr., 5/6; 1 gr. 10/0
In amœbic dysentery, often in conjunction with Auremetine.

GLUCOSE SOLUTION, *Conc., for producing 1 pint of 5% solution for intravenous feeding* ... ... Each 2/6

GUAIACOL, IODINE AND CAMPHOR, *in rheumatoid arthritis.* Box of 10 5/6

GUM SOLUTION, *Conc. (intrav.), for surgical shock* ... Each 2/6

HYDRARG. SALICYL-ARSENATE, *in syphilis*, 1 grain. Box of 10 5/6

INDIGO-CARMINE *(intrav.). Renal indicator.* 1%, 5 c.c. 5/6; 10 c.c. Box of 10 7/6

MANGANESE BUTYRATE *(intram.), in furunculosis, boils, etc.*, 1% 1 c c. Box of 10 4/6

PEPTONE FOR ASTHMA, *series of 10 graded doses, intravenous and intramuscular. (See special leaflet.)* ... ... Box of 10 7/6

PHENOLSULPHONEPHTHALEIN, 6 mgr., *for Kidney Test* Box of 10 7/6

PITUITARY (Infundibular) *(intram.)*, ½ c c., 6/0; 1 c.c. Box of 10 10 0

QUININE-URETHANE, *in varicose veins* ... 2 c.c. Box of 10 5 0

SODIUM CACODYLATE, 1 grain *in* Nucleinic Acid Solution 1 c c, *in Septicæmia* ... ... Box of 10 5/6

SODIUM NUCLEINATE *(hypod. and intram.), in acute fevers, pneumonia, etc.* .. .. 5%, 1 c.c Box of 10 3 6

SODIUM THIOSULPHATE, 0.45 and 0.6 gm , in 5 c c. *Intrav. in Arsenical and Mercurial poisoning* ... ... Box of 10 6 6

STOVAINE-GLUCOSE, aa., 5%, 1 c c., 6/6 ... 2 c.c. Box of 10 10 0

THIOSINAMIN COMP. *(intram., hypod. or intrav.), for keloid, scar tissue, etc.*, 1 c.c., 5/6 ... ... 2·5 c c. Box of 10 7 6

"STERULES" to special formulæ, any size up to 100 c.c., are prepared promptly.

Further list on application. You may rely on immediate attention to postal enquiries. Please mention the *B.M.J.* when replying.

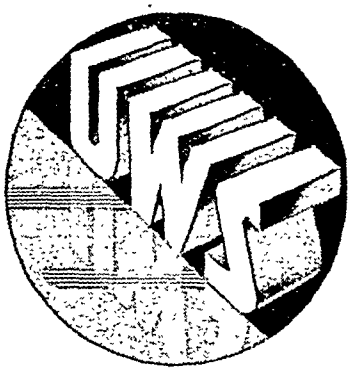
THE MOST SATISFACTORY METHOD OF ENSURING A SOFT WATER SUPPLY



It is a fact of considerable significance that 'Permutit' Water Softening Plants are to-day to be found in over 15,000 homes, and in the leading hospitals, clubs and hotels. No chemicals are used in the 'Permutit' System. This plant provides a soft water which is healthful and palatable to drink, at a moderate initial outlay and an infinitesimal running cost. The plant can be fitted without any alteration to existing arrangements.

Special Booklet Sent Free on Request
"Soft Water in the Home," an illustrated sixty-four page booklet, will gladly be sent to any doctor upon request.

'PERMUTIT' REGD
WATER SOFTENER

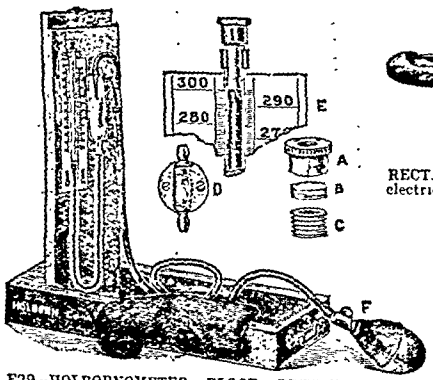
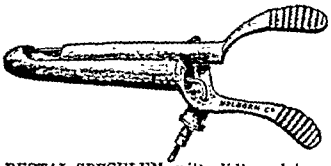
THE HOLBORN SURGICAL INSTRUMENT CO., LTD.,

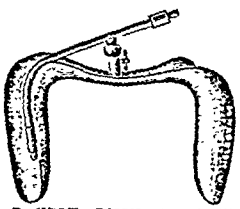
26, THAVIES INN, LONDON, E.C.1 Tel. No.: Central 5096.



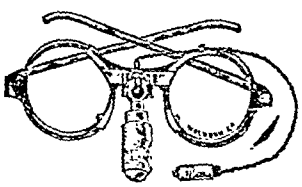
E29—HOLBORNOMETER BLOOD PRESSURE APPARATUS, with wide column and unspillable tube in polished oak case £4 10 0.
Details on application.



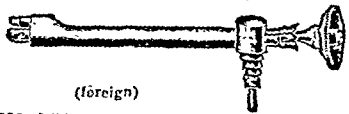
RECTAL SPECULUM, with sliding plate and electric attachment fitting battery handle. £1 7 6.



SIMS' DOUBLE DUCKBILL SPECULUM, with electric attachment on ball-and-socket fitting. 25/-.

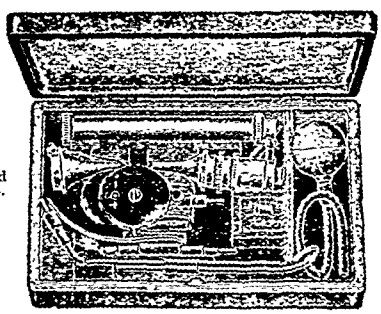


H94—"SPECLITE," with special filament bulb, Ever Ready Battery in case with screw fitting, £1 7 6. Leather case, 7/6 extra.



(foreign)

B298—BECK'S LARYNGO - PHARYNGOSCOPE, £3 15 0.
With nickel-plated battery handle and spare lamp in case £5 5 0.
The single lamp gives a brilliant illumination of the cavity and renders obsolete the double-lamp type of pharyngoscope. The telescope shows a large clear field, so that the entire side of the pharyngeal vault can be examined at one time.



H75A

H75A—DIAGNOSTIC OUTFIT consisting of Wappler Auriscope with three Specular, May Ophthalmoscope, Nasal Speculum fitting Auriscope body, Laryngeal Mirror and Tongue Depressor with light attachments all fitting battery handle, complete, in case with three spare lamps and Suction Ball, £8 0 0.

H75B—DITTO. Without Tongue Depressor, £7 5 0.

H75C—Combined Set, AURISCOPE and OPHTHALMOSCOPE, best quality, with spare lamps, complete in case, £5 5 0.

H75—MAY'S OPHTHALMOSCOPE, best quality, with handle and spare lamp, in leather case, £3 3 0.

The above are supplied with medium-size handle, black or nickel-plated.

H76—WAPPLER MODEL AURISCOPE, with 3 specular and small handle, in case, 52/6. DITTO, with medium handle and spare lamp, £2 18 0.

AURISCOPE and one speculum, with Ever Ready Torch handle, £1 7 6.

PHYSIOLOGICAL and SURGICAL SUPPORTS

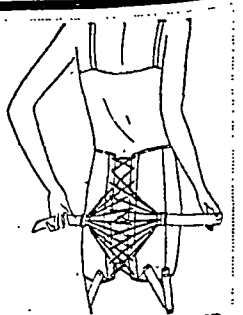
A New and Growing Field of Service

APPROVED by eminent Physicians and Surgeons

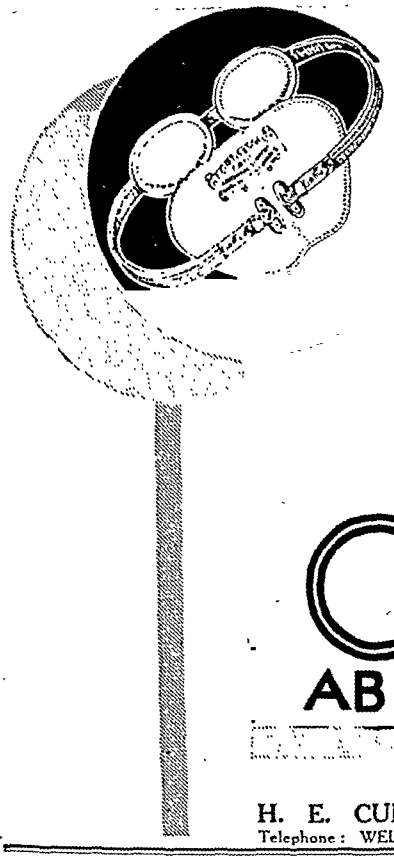
Camp Supports are widely used in the treatment of
SACRO-ILIAC SPRAIN, PTOSIS, HERNIA, MATERNITY and POST-OPERATIVE SUPPORT

Illustrated CAMP MANUAL *free on request to:—*

CAMPOIRETTE Ltd., 252, REGENT ST., LONDON, W.1



THE CAMP PATENTED Adjustment—instantaneous and simple in action.



Comfortable and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

CURTIS
ABDOMINAL SUPPORT

Sole Manufacturers of the Curtis Appliances:—

H. E. CURTIS & SON LTD., 7, Mandeville Place, London, W.1.

RE-INFORCING THE ABDOMINAL MUSCLES WITHOUT UNDUE PRESSURE!

For those disorders of the abdomen that call for external support, Domen Abdominal Belts have very definite advantages. They give adequate support to the abdomen without setting up pressure to aggravate the patient's condition. And whether it is pregnancy or umbilical hernia, prolapsus uteri, or simply general support, there is a Domen Belt designed specifically for that condition. Domen Belts fit well, sit comfortably and do not get out of place. They leave the patient free and without embarrassment. Full particulars will be forwarded on receipt of your card or a telephoned request.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-therapeutic treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Billiards, tennis, etc. Fees from five guineas per week.

Apply, Dr. D. E. M. DOUGLAS-MORRIS *Telephone*: Newport Pagnell 121.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

The MAUDSLEY HOSPITAL
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841—2.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.

IN-PATIENTS: (*a*) 189 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (for ladies) with special sitting room, garden, and dietary.

TERMS:

(*a*) £5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.

(*b*) £6 6s. a week.

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., F.R.C.P., F.R.C.S., Medical Superintendent.

BARNWOOD HOUSE,
GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L. M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.

For particulars as to terms, etc., apply to—
ARTHUR TOWNSEND, M.D., Resident Supt.
Telephone: No. 7 Barnwood.

BOURNEMOUTH.

F. J. SYMONS,
January 29th, 1931. Secretary.

Nottinghamshire County Council

RANSOM SANATORIUM.

APPOINTMENT OF MEDICAL SUPERINTENDENT.

The Nottinghamshire County Council invite applications from duly qualified and registered Medical Practitioners for the appointment of Medical Superintendent at the County Sanatorium, Sherwood Forest (130 beds, 50 male, 40 female, and 40 children).

The salary attaching to the position will be £650 per annum, with emoluments valued at £100 (furnished married quarters, fuel, light, water), rising by biennial increments of £50 to £838 with emoluments, and the appointment will be terminable on three months' notice.

The person appointed will reside at the Sanatorium and, subject to the general direction and control of the County Medical Officer of Health, he will be required to take full responsibility for the administration of the Sanatorium, the supervision of the Staff, and the treatment of patients.

The appointment is an established post under the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Forms of application, details of duties, and qualifications for the appointment may be obtained upon application at my office at the undermentioned address, and applications, with copies of not more than three recent testimonials, must be addressed to the County Medical Officer, Shire Hall, Nottingham, not later than Thursday, February 12th.

K. TWEEDALE MEABY,
Clerk of the County Council.

County House,
Nottingham.
January, 1931.

Nottinghamshire County Council

EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER (Male).

Applications are invited from duly qualified and registered Medical Practitioners for the post of Assistant School Medical Officer.

Candidates must possess a Diploma in Public Health and have had at least three years' experience since qualification. Knowledge of Refractions and Mental Deficiency will be deemed additional qualifications.

The officer appointed will be required to devote his whole time to the duties of the office. He will be a member of the staff of the County Medical Officer, will work under his control and direction, and will be required to reside in a part of the County to be approved by him and to carry out such duties as may be prescribed.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700, with travelling allowances in accordance with the County Council's Scale.

The engagement will be terminable by three months' notice on either side.

The appointment is an established post under the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned and should be returned, accompanied by copies of not more than three recent testimonials, to the County Medical Officer, The Shire Hall, Nottingham, on or before Feb. 18th.

K. TWEEDALE MEABY,
Clerk of the County Council.

Shire Hall,
Nottingham.

Bedfordshire County Council.

DEPUTY COUNTY MEDICAL OFFICER OF HEALTH AND SENIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified and registered male Medical Practitioners for the above appointment. Applicants must possess a Diploma of Public Health, and have had at least 5 years' experience in the Medical Inspection of School Children.

The salary for the appointment will be £750 per annum, together with a travelling allowance of £170 per annum.

If the person appointed possesses experience in the modern methods of the diagnosis and treatment of venereal diseases, he would be eligible for an appointment in this branch of the Council's Medical Service.

Applications, endorsed "Deputy County Medical Officer," setting out qualifications, experience, etc., with copies of not less than three recent testimonials, to be delivered to the undersigned not later than February 14th, 1931.

J. B. GRAHAM,
Clerk of the County Council.

Shire Hall,
Bedford.
January, 1931.

Nottinghamshire County Council

APPOINTMENT OF SCHOOL DENTIST (Male).

Applications are invited for the appointment of a Whole-time School Dentist, at a salary of £500 per annum, rising after completion of two years' satisfactory service by increments of £25 annually to a maximum of £550. Travelling expenses will be paid in addition according to the Scale approved by the County Council.

Candidates must be fully qualified and registered Dental Surgeons, and the person appointed will be required to perform such duties as may be from time to time prescribed by the County Education Committee, and to devote his whole time to the duties of the office. He will be a member of the Staff and act under the control and direction of the County Medical Officer of Health, and required to reside in a part of the County to be approved by the Education Committee.

The appointment will be terminable by three months' notice on either side.

The successful candidate will be required to pass a medical examination.

The appointment is an established post under the Local Government and Other Officers Superannuation Act, 1922.

Applications on the prescribed form (which may be obtained on application to me), accompanied by copies of not more than three recent testimonials, should be forwarded to the County Medical Officer, Shire Hall, Nottingham, not later than February 18th.

K. TWEEDALE MEABY,
Clerk of the County Council.

Shire Hall,
Nottingham.
January, 1931.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of a Male Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the medical inspection of school children, maternity and child welfare, and the treatment of tuberculosis and venereal diseases. The officer appointed will be required to undertake such other Public Health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Minister of Health, to the provisions of the Local Government, and Other Officers Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form, and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day of receipt of applications, Wednesday, February 18th. Canvassing, directly or indirectly, will disqualify.

DUDLEY AUKLAND,
Clerk of the County Council.

County Hall,
Kingston-on-Thames.
January 27th, 1931.

Kent County Council.

MENTAL DEFICIENCY.

LEYBOURNE GRANGE.

APPOINTMENT OF RESIDENT MEDICAL SUPERINTENDENT.

Applications are invited for the position of Resident Medical Superintendent of the Institution for Mental Defectives to be opened at Leybourne Grange, near Maidstone. The Institution will accommodate 94 female defectives of the higher grades and will form the nucleus of a colony for mental defectives.

Candidates must not be more than 45 years of age, must be male registered Medical Practitioners, and must have had previous experience in the institutional care and treatment of mental defectives.

The salary will be £700 per annum, rising by annual increments of £25 per annum to £1,000 per annum. The emoluments will consist of an unfurnished house, lighting, fuel, water, garden produce, and laundry for self and family, and will be valued for pension purposes at £300 per annum.

Forms of application, with further particulars, can be obtained from the undersigned, and must be completed and returned to him not later than February 21st.

W. L. PLATTS,
Clerk of the Kent County Council.

Sessions House, Maidstone.
January 27th, 1931.

City of Birmingham.

ERDINGTON HOUSE.

RESIDENT MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners, male, with experience in the special duties to be performed, for the appointment of Medical Officer (whole time) of the Erdington House Poor Law Institution and its Annexe, Witton Hall, and of the Erdington Children's Homes.

The Institution and Annexe has accommodation for 1,980 patients, of whom approximately 1,000 are mental patients, some being certified for detention under the Lunacy Act, others under the Mental Deficiency Acts. About 250 are in sick wards, the remainder being aged and infirm, ordinary house cases, etc. The Children's Homes (grouped) have accommodation for 379. The Medical Staff comprises the Medical Officer and two resident Assistants, one male and one female.

The total salary for the appointment is £850 per annum, together with furnished house, rations, lighting, heating, laundry, and attendance, the emoluments being valued for superannuation purposes at £250 per annum. The whole is subject to superannuation deductions.

The gentleman appointed may be required to perform the duties of Public Vaccinator in respect of the two Institutions, but any fees from this source, as well as fees under the Lunacy Acts, and all other fees or payments received by the Officer are required to be paid into the Corporation funds.

The appointment will be subject to satisfactory medical examination.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be sent to the undersigned on or before Wednesday, February 11th.

Council House, F. H. C. WILTSHIRE,
Birmingham. Town Clerk.
January 26th, 1931.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BOOTH HALL HOSPITAL.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

The Public Health Committee invites applications for the appointment of Woman Assistant Medical Officer at the Booth Hall Hospital for Children (750 beds), Charlestown Rd., Blackley, Manchester.

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants with previous Hospital experience.

The Hospital is a recognized Training School for Nurses and is equipped with all modern Hospital requirements.

Salary £250 per annum, with board, residence, and laundry in addition. No bonus.

The appointment will be made, in the first instance, for a period of six months. The successful candidate, however, will be eligible for re-appointment for a further period of six months at the end of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and her age, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Officer, Booth Hall Hospital," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Friday, February 13th.

The candidate appointed will be required to commence duty as soon as possible after appointment, to devote the whole of her time to the duties of the position, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

Town Hall, F. E. WARBRECK HOWELL,
Manchester. January 30th, 1931. Town Clerk.

The King Edward VII Welsh NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered Medical Practitioners (male) for the post of THIRD ASSISTANT RESIDENT MEDICAL OFFICER at the NORTH WALES SANATORIUM, LLANGWYFAN, near Denbigh. (256 beds for pulmonary and non-pulmonary cases.)

Salary £250 per annum, plus full maintenance, etc., the appointment being limited to one year.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should reach the undersigned not later than February 12th.

Memorial Offices, D. A. POWELL,
Westgate Street, Principal Medical
Cardiff. Officer.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A RESIDENT MEDICAL SUPERINTENDENT is required on March 9th.

Gentlemen are invited to send in their application to the Secretary, before 12 o'clock on Monday, March 2nd, accompanied by copies of not more than three testimonials given specially for the purpose.

The appointment is made for one year, but may be held, subject to re-election, for a period of three years.

Salary £300 per annum, with board-residence in the Hospital, £10 allowance for laundry, and £18 18s. for the purpose of providing a substitute during annual leave.

Candidates must be unmarried and possess a legal qualification to practice, and must have held a responsible Hospital appointment at a General Hospital.

All candidates must be in attendance on Wednesday, March 4th, at 4.45 p.m. precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the Rules may be obtained from the Secretary at the Hospital.

By Order of the Board of Management,
JAMES McKAY,
February, 1931. Secretary.

Cumberland and Westmorland
MENTAL HOSPITAL, GARLANDS, CARLISLE.

JUNIOR ASSISTANT MEDICAL OFFICER required.

Applicants must be registered Practitioners, male, unmarried, not over 30. Salary £350 per annum, rising by four annual instalments of £25 to £450, together with the usual emoluments, valued for the purpose of the A.O.S. Act at £100 per annum. £50 additional will be given on obtaining the D.P.M. The appointment to be subject to two months' notice on either side. The successful candidate to be free to take up duty shortly after March 1st.

Applications, stating age, qualifications, religion, etc., together with copies of three recent testimonials, to reach the undermentioned not later than February 19th.
